Precision Medicine Implementation

Prediction

- Disease
 - risk stratification
 - intervention strategies
- Adverse events
- Efficacy of treatment

Dissection

- Etiology of complex traits
- Mechanism by which genetic variation drives phenotypic variation
- Druggable targets

The Promise of the Human Genome Sequencing Project

- In year 2000, president Clinton announced the completion of the first draft of the human genome, which would "revolutionize the diagnosis, prevention, and treatment of most, if not all, human diseases.
- Francis Collins predicted that diagnosis of genetic diseases would be accomplished by 2010 and that treatments would start to roll out perhaps by 2015.
- Why are we not there yet?

OmicKriging: Integration of Multiple Omics Data

Genetic Epidemiology 2014

What is Kriging?

What is Kriging?

Kriging

Predicted Y is the weighted average of the observations

$$\text{Prediction}(Y_{\text{new}}) = \omega_1 Y_1 + \omega_2 Y_2 + \cdots + \omega_n Y_n$$

$$\omega_i = \text{function}(\text{all } n(n+1)/2 \text{ pairs of correlations})$$

Without covariates

$$\omega' = \rho' \Sigma^{-1}$$

ρ the correlation between the new value and the observed values and

Σ the correlation matrix of the observations.

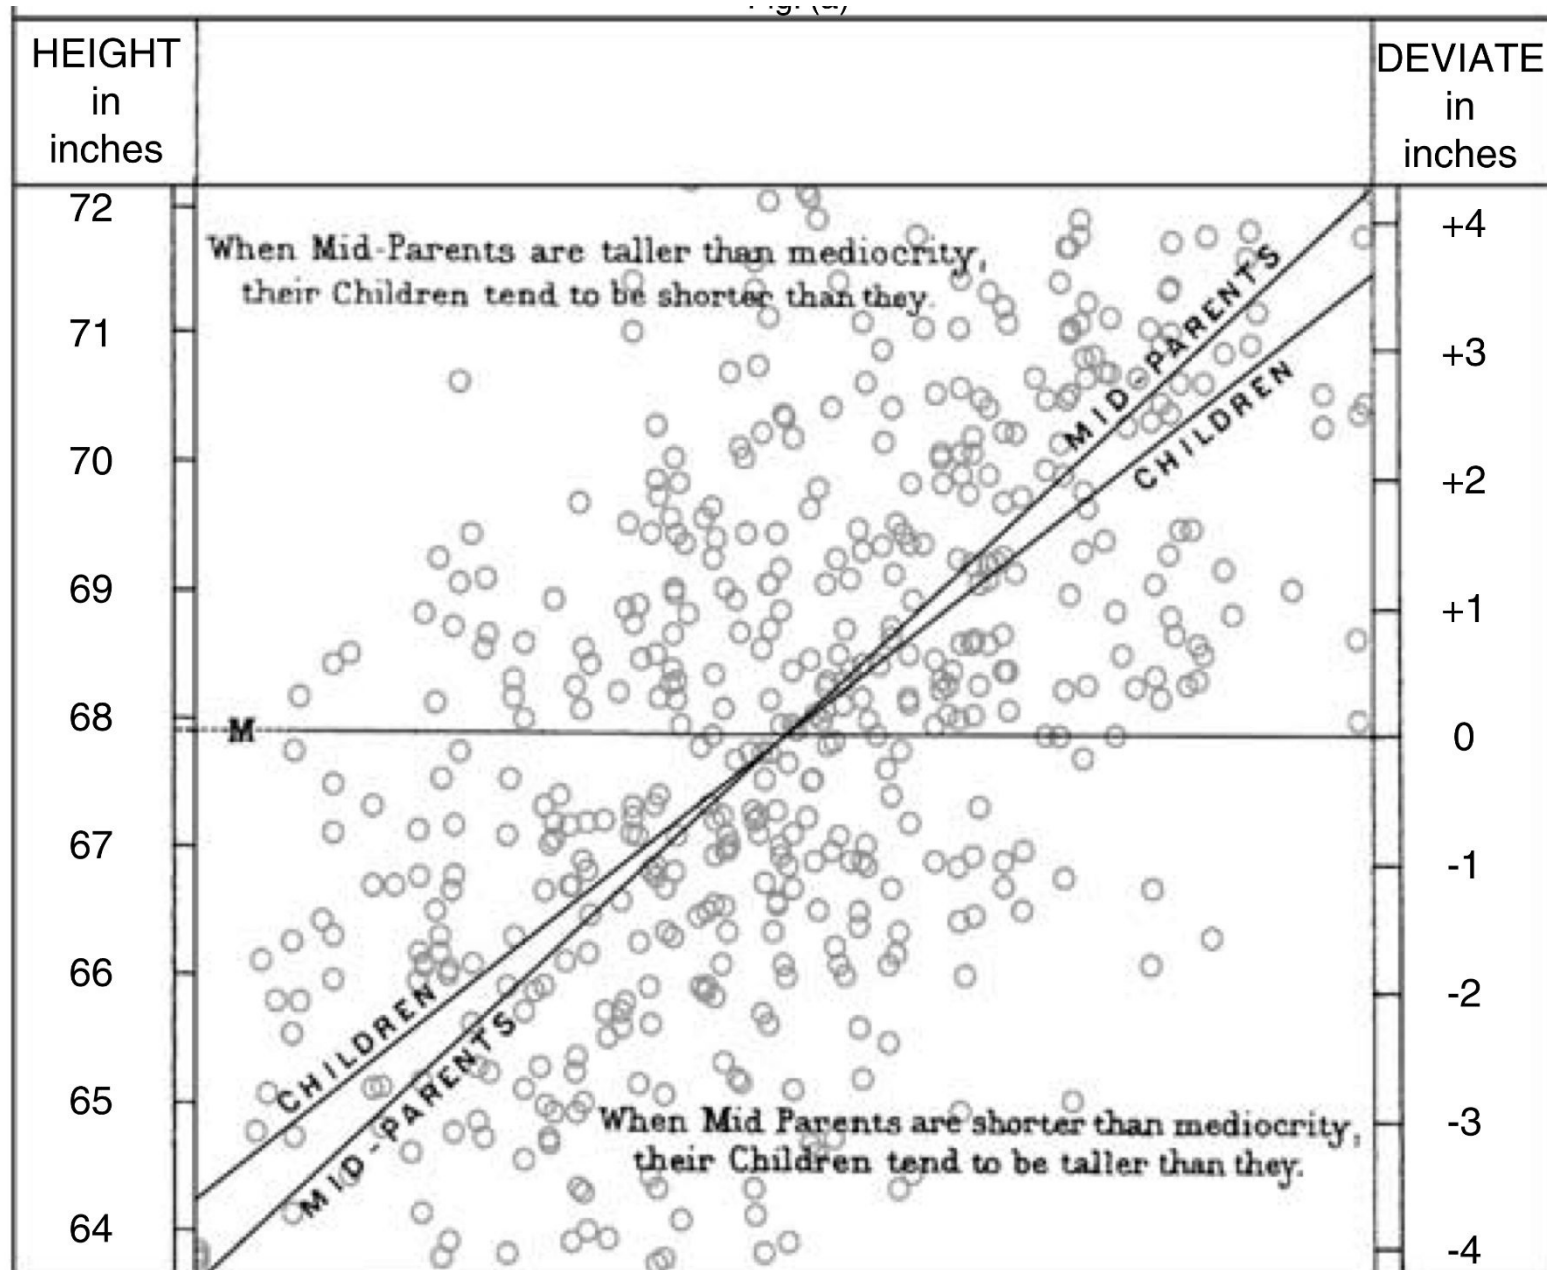

Galton's Height Data

FAMILY HEIGHTS. from R.F.F.
(add 60 inches to every entry in the Table)

	Father	Mother	Sons in order of height	Daughters in order of height.

Galton Was Kriging with Kinship Matrix (1885)

Kriging = BLUP (Best Linear Unbiased Prediction)

- Galton (1885): parent to offspring
- Fisher (1918) and Wright (1921): pedigree
- Formalized by Henderson (1950,1975) and Goldberger (1962)
- G-BLUP: genetic relatedness estimated using genotype
- BLUP/Kriging can be interpreted as the posterior mean of the genetic component given observations ($Y = G + \text{error}$)

Kriging = BLUP (Best Linear Unbiased Prediction)

- Galton (1885): parent to offspring
- Fisher (1918) and Wright (1921): pedigree
- Formalized by Henderson (1950, 1975) and Goldberger (1962)
- G-BLUP: genetic relatedness estimated using genotype
- BLUP/Kriging can be interpreted as the posterior mean of the genetic component given observations ($Y = G + \text{error}$)

**BLUP/Kriging translates genetic similarity
into phenotypic prediction**

Polyomic Model

$$Y_i = a + G_i + T_i + O_i + \epsilon_i$$

$$G_i = \sum_{l=1}^M \beta_l^G x_{il}^G$$

genetic component

$$T_i = \sum_{l=1}^L \beta_l^T x_{il}^T$$

transcriptomic component

$$O_i = \sum_{l=1}^{L'} \beta_l^O x_{il}^O$$

other omic component

$$(\beta_G, \beta_T, \beta_O)' \sim N(0, \Sigma_\beta)$$

Optimal Similarity Matrix

$$Y_i = a + G_i + T_i + O_i + \epsilon_i$$

Assuming independence of β 's

$$\Sigma_{i,j} = \theta_G \sum_{l=1}^M X_{il}^G X_{jl}^G + \theta_T \sum_{l=1}^L X_{il}^T X_{jl}^T + \theta_O \sum_{l=1}^{L'} X_{il}^O X_{jl}^O + \theta_\epsilon \delta_{ij}$$

More generally

$$\begin{aligned} \Sigma_{i,j} = & \theta_G \sum_{l=1}^M X_{il}^G X_{jl}^G + \theta_T \sum_{l=1}^L X_{il}^T X_{jl}^T + \theta_O \sum_{k=1}^{L'} X_{ik}^O X_{jk}^O + \theta_\epsilon \delta_{ij} \\ & + \sum_{k \neq l} \text{cov}(\beta_k, \beta_l) X_{ik} X_{jl} \end{aligned}$$

Application of OmicKriging to Cellular Growth

OmicKriging R Package

The screenshot shows a web browser window titled "CRAN - Package OmicKriging". The address bar shows the URL "cran.r-project.org/web/packages/OmicKriging/index.html". The browser has several tabs open, including "Proxyt!", "webshare", "Spanish", "English", "Korean", "AmazonSmile", "Read Now", "Read Later", "Save to Mendeley", and "Apple". The main content area displays the package information for OmicKriging.

OmicKriging: OmicKriging for Phenotypic Prediction

This package provides functions to generate a correlation matrix from a genetic dataset and to use this matrix to predict the phenotype of an individual by using the phenotypes of the remaining individuals through kriging. Kriging is a geostatistical method for optimal prediction or best unbiased linear prediction. It consists of predicting the value of a variable at an unobserved location as a weighted sum of the variable at observed locations. Intuitively, it works as a reverse linear regression: instead of computing correlation (univariate regression coefficients are simply scaled correlation) between a dependent variable Y and independent variables X, it uses known correlation between X and Y to predict Y.

ABSTRACT: High-confidence prediction of complex traits such as disease risk or drug response is an ultimate goal of personalized medicine. Although genome-wide association studies have discovered thousands of well-replicated polymorphisms, the prediction of complex traits remains a challenge. OmicKriging is a novel method that combines information from multiple omics data to improve the prediction of complex traits. It is based on the principle that the same genetic variant can have different effects on different traits, and that the same trait can be influenced by different genetic variants. OmicKriging uses a Bayesian framework to model the relationships between genetic variants and traits, and to predict the effect of a given variant on a given trait. The method is applied to a set of simulated data, and the results show that OmicKriging outperforms other methods in terms of prediction accuracy. The method is also applied to real-world data, and the results show that OmicKriging is able to predict complex traits with high accuracy. The method is available as an R package, and the source code is available on GitHub.

Summary OmicKriging

- OmicKriging is a systems approach to complex trait prediction that leverages and integrates multiple omic data
- We can attain relevant prediction even if we do not know the individual variant's contribution
- Important tool for integrating the vast amounts of data to be generated with the precision medicine initiative

Role of Regulatory Variation in Complex Traits

Mechanism of Genotype to Phenotype Link

- Most trait-associated SNPs are not coding
- Mechanism via regulation of gene expression levels

Altered Protein Levels Influences Disease Risk

Albert & Kruglyak 2015 NGReviews

Regulatory variants explain much more heritability than coding variants across 11 common diseases

PrediXcan: Mechanism-driven Gene-Based Test

- Directly tests the molecular mechanism through which genetic variants affect phenotype
- Genes more attractive than genetic variants
 - A lot is known about their function
 - Follow up experiments can be easily devised
 - Reduced multiple testing burden
- Direction of effects
 - Positive effects: down regulation is therapeutic option
 - Negative effects: more likely to harbor deleterious rare variants
- No reverse causality issues
- Can be systematically applied to existing GWAS studies
- Tissue-specificity can be inferred

Reference Transcriptome Data

PrediXcan: a Gene Discovery Approach

- PrediXcan is a powerful gene based association test
- It directly tests the molecular mechanism through which genetic variants affect phenotype
- Reduced multiple testing burden compared to single variant approach
- Unlike other gene based tests, it provides direction of effects
- Advantages relative to gene expression studies
 - Applicable to any GWAS datasets
gene expression levels are predicted from genotype data
 - No reverse causality
disease status does not affect germline DNA
 - Multiple Tissues can be evaluated
tissue expressions are only needed to build prediction models

Prediction of Gene Expression Traits

Genetic Architecture to Improve Prediction

- Local and distant regulation (heritability)
- Sparsity/Polygenicity
- This information guides us to improve prediction, i.e. estimates of GReX

Local/Distant Heritability Estimation

- Gene expression trait model

$$Y = \sum_{\text{local}} \beta_k^{\text{local}} X_k + \sum_{\text{distant}} \beta_k^{\text{distant}} X_k + \epsilon$$

- REML to estimation of local and distant contributions jointly
- Covariance of local component: GRM using SNPs nearby
- Covariance of distant component: GRM using distant SNPs
- We use GCTA as REML calculator

Total Heritability = Local H2 + Distant H2

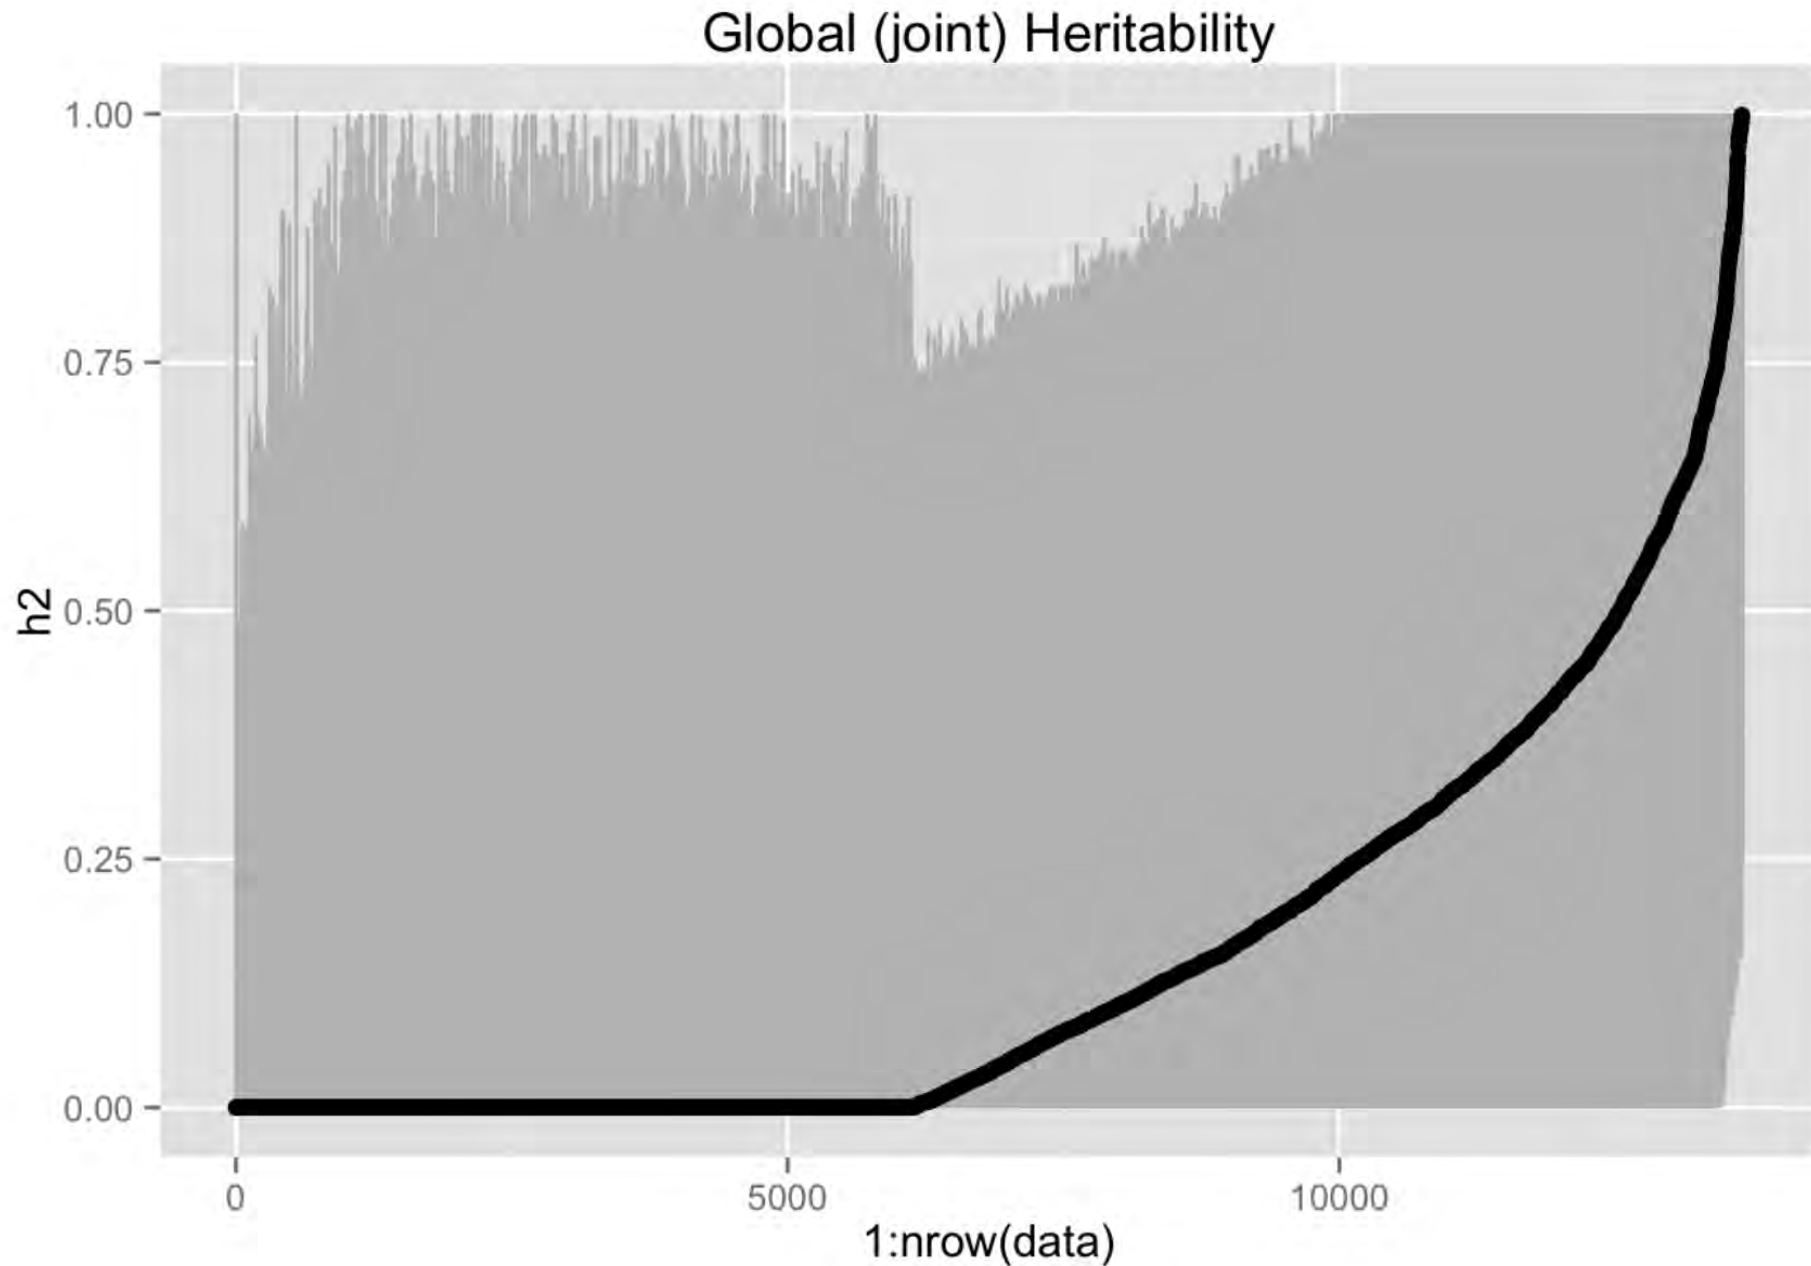

Whole Blood Expression Data: DGN

- Battle et al. “Characterizing the genetic basis of transcriptome diversity through RNA-sequencing of 922 individuals.” Genome Research 2014, 24(1):14-24
- Whole blood from Depression Genes and Networks study
- n = 922
- RNA-seq

Local Heritability Can Be Well Estimated

Distant Heritability Not Reliable

Proportion of LASSO to Ridge as Measure of Sparsity

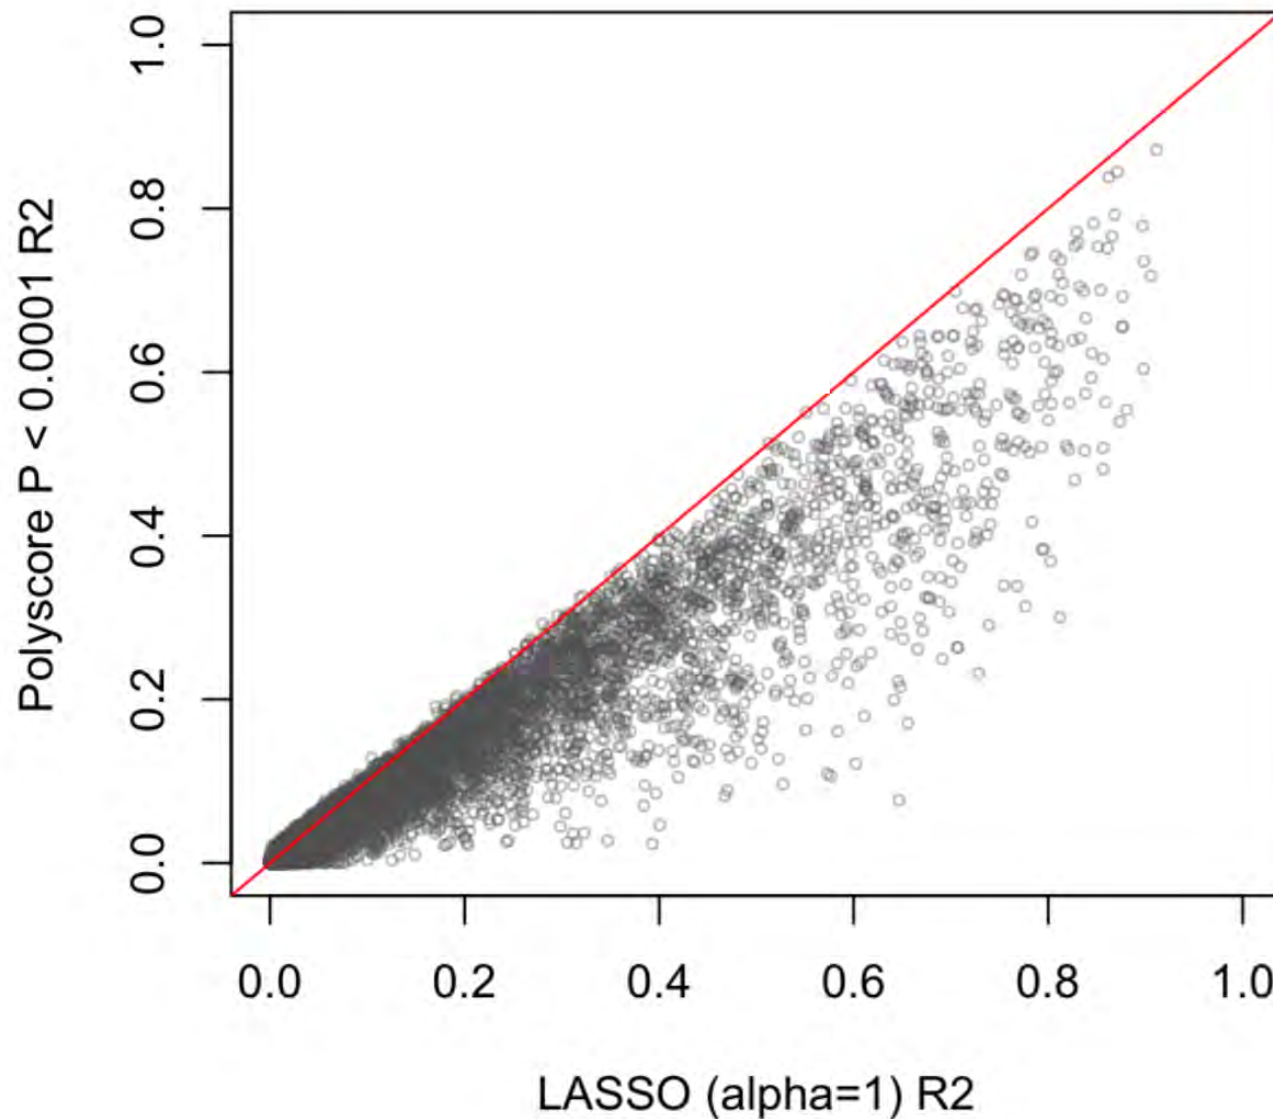

- Only local component can be assessed
- LASSO performs slightly better than E-N 0.50 in cross validated R^2

Performance vs sparsity

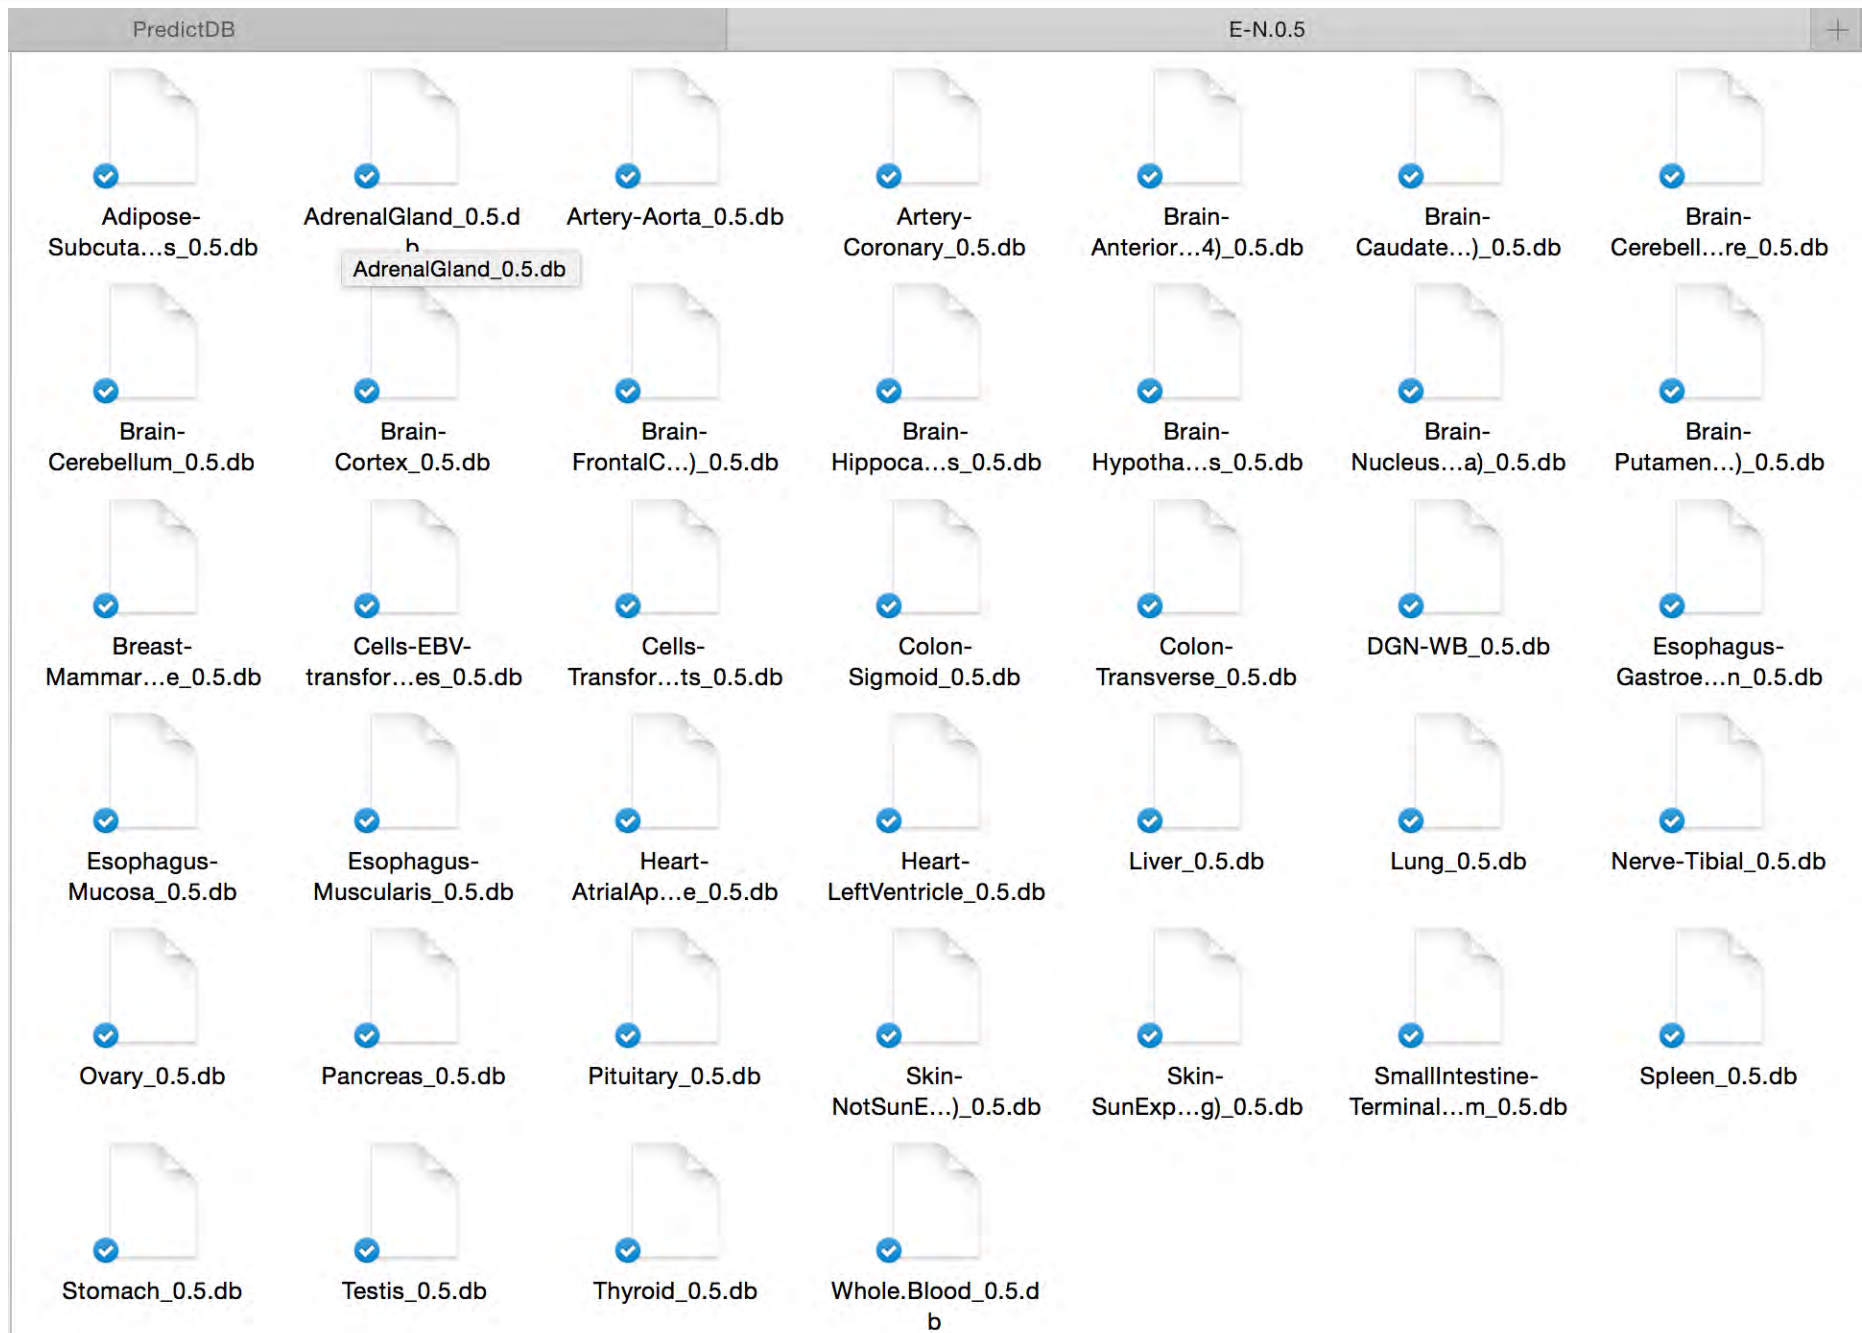

E-N & LASSO Outperform Polygenic Score

DGN-WB predictive performance

Whole Blood DGN (n=922) + 38 GTEx Tissue Models

Challenges in Pharmacogenomic Predictions

Pharmacogenomic Findings

Evidence Level	Counts	%
1a	40	3
1b	17	1
2a	96	6
2b	74	5
3	1175	76
4	145	9
Total	1547	100

<https://www.pharmgkb.org/>

Challenges of Pharmacogenomic Studies

- Smaller sample size
- Even more important to integrate prior data
- Integrate other functional data
- Heritability estimates are harder
 - Limited family data
 - Usually samples greater than 1K are needed for GCTA

Bevacizumab Induced Hypertension

- Bevacizumab is a humanized monoclonal antibody that inhibits VEGF induced angiogenesis
- Hypertension is a common adverse event to bevacizumab treatment
- The incidence of hypertension with bevacizumab is 20-30%, while grade 3 or greater hypertension occurs in only 10-15% of patients.

Keston Aquino Michaels

Bevacizumab Trials

- CALGB 90401
 - a randomized double-blinded placebo controlled phase III trial comparing docetaxel and prednisone with and without bevacizumab in men with hormone refractory prostate cancer
 - n = 664 (with genotype data after QC)
 - PI: Howard McLeod
- CALGB 80303
 - a randomized phase III trial of gemcitabine plus bevacizumab versus gemcitabine plus placebo in patients with advanced pancreatic cancer
 - n = 152 (with genotype data after QC)
 - PI: Federico Innocenti

Bevacizumab Induced Hypertension

- Is primary hypertension risk score predictive of bevacizumab induced hypertension
 - Hypertension results from Cross Consortia Pleiotropy group (n~20K)
- Can we predict drug induced hypertension?
 - 90401 training set
 - 80303 test set

Keston Aquino Michaels & Heather Wheeler

Primary Hypertension Score Predicts Bev-induced HT

Keston Aquino Michaels

Bev-Hypertension Predicted Within Study

Keston Aquino Michaels

Bev-Hypertension Predicted in Independent Study

Keston Aquino Michaels

Bev-Hypertension Predicted in Independent Study

Summary Pharmacogenomics

- Most single variant findings have limited clinical utility
- Whole genome approaches to prediction improves utility
- Bevacizumab induced hypertension example
 - primary hypertension results help in predicting drug induced hypertension
 - successfully predicted bevacizumab induced hypertension in independent study
 - combining primary + bevacizumab induced HT leads to improved prediction

Summary

- Shift from monogenic to polygenic paradigm
- Systems approach to genomics
 - Most single variant findings have limited clinical utility
 - Whole genome approaches to prediction improves utility
- Larger sample sizes will be needed, 1Million+
- OmicKriging: prediction method that integrates heterogeneous sources of data well suited for data from the Precision Medicine Initiative
- Large role of regulation variants in complex traits
- PrediXcan: novel gene based test that test mechanism
- Prediction of gene expression traits

Conclusion

- recognizing the complexity of the genetic architecture and mechanisms of genetic control,
- collecting deep phenotype data from large number of individuals,
- broadly sharing data and results, and
- integrating multiple sources of data
- using mechanism-driven tests

We will achieve the promise of precision medicine

Thank You!
