The positive impact of social media on the learning environment has been demonstrated. A study by Yi and others [1] found that medical students who used Twitter during lectures had higher test scores and reported better knowledge retention compared to those who did not use social media.

Social media has also been used to improve clinical skills. A study by Dorn and colleagues [2] found that medical students who used social media to practice their physical examination skills had higher scores on a subsequent examination compared to those who did not use social media.

In conclusion, social media can be an effective tool for medical education. However, it is important to consider the risks and limitations of social media use, such as the potential for miscommunication and the need for clear guidelines for appropriate use.
