1 Topic and map document types

The Technical Content package contains various document types: concept, glossary entry, glossary group, reference, general task, strict task, and troubleshooting. The package also includes the book map document type.

1.1 Glossary entry

A glossary entry topic defines a single meaning of a term. It also can provide information such as acronyms and synonyms.

Purpose

Glossary entry topics serve the following purposes:

- They ensure that a team of writers can use the same terminology.
- They can be used to create glossaries that provide readers with definitions of terms and acronyms.
- They can be used, in conjunction with the `<abbreviated-form>` element, to enable processors to specify an acronym on second and later uses of a term.

Content model

Each glossary entry topic contains the following structures:

- Term: `<glossterm>` (13)
- Definition of term: `<glossdef>` (9)
- Glossary body: `<glossBody>` (8)

Examples

This section contains examples of glossary entry topics.

Figure 1: Simple glossary entry topic

The following code sample contains a simple glossary entry topic:

```xml
<glossentry id="ddl">
  <glossterm>data definition language</glossterm>
  <glossdef>A language used for defining database schemas</glossdef>
</glossentry>
```

Figure 2: Glossary entry topic used for acronym and acronym expansion

The following code sample contains a glossary entry topic that is used, in conjunction with an `<abbreviated-form>` element, to render the expanded form on first usage and the acronym on later usages.

```xml
<glossentry id="glossary-aids">
  <glossterm>acquired immunodeficiency syndrome</glossterm>
  <glossSurfaceForm>acquired immunodeficiency syndrome (AIDS)</glossSurfaceForm>
  <glossAlt><glossAcronym>AIDS</glossAcronym></glossAlt>
</glossentry>
```
Assume that a key-definition map specifies a value of "aids" for this glossary entry topic. On the first usage of `<abbreviated-form keyref="aids"/>`, the processor renders the content of the `<glossSurfaceForm>` element. On the second and later usages, the processor renders the content of the `<glossAcronum>` element.

1.2 Glossary group

Glossary group topics enable the authoring of glossary entries in a single topic document, rather than working with many individual glossary-entry topic documents.

**Purpose**

The glossary group topic serves as an authoring convenience. It enables people to author and manage multiple glossary-entry topics in a single DITA document.

**Content model**

A glossary group topic can contain multiple glossary-entry topics.

**Example**

The following code sample shows a glossary group topic with multiple nested glossary groups, one for each English letter group.

```xml
<glossgroup id="glossgroup" xml:lang="en-US">
  <glossgroup id="glossgroup-a">
    <title>A</title>
    <glossentry id="apple-fruit">
      <glossterm>apple</glossterm>
      <glossdef>A round, edible fruit produced by an apple tree (Malus domestica).</glossdef>
    </glossentry>
    <glossentry id="apple-corp">
      <glossterm>Apple Inc.</glossterm>
      <glossdef>An American multinational technology company headquartered in Cupertino, California.</glossdef>
    </glossentry>
  </glossgroup>
  ... (groups B to Y here ) ...
  <glossgroup id="glossgroup-z">
    <title>Z</title>
    <glossentry id="ziziphus-fruit">
      <glossterm>ziziphus</glossterm>
      <glossdef>The edible drupe of ziziphus shrubs (Ziziphus jujuba).</glossdef>
    </glossentry>
    <glossSynonym>jujube</glossSynonym>
  </glossgroup>
</glossgroup>
```
2 Usage of glossary entry topics

Glossary entry topics are designed for several purposes. In addition to providing the basis for glossaries, they also can be used in conjunction with the abbreviated-form domain to provide different renderings of terms on first and later usage.

2.1 Rendering of <abbreviated-form> elements

The <abbreviated-form> element is designed to work with glossary entry topics in specific ways.

Consider the following scenario:

A DITA publication contains several instances of <abbreviated-form> elements. Each <abbreviated-form> element references the same DITA topic.

The design intent is that processors use the following logic:

1. If the referenced topic is not a <glossentry> topic or a specialization of <glossentry>, the title of the topic SHOULD be rendered.
2. If the referenced topic is a <glossentry> topic or a specialization of <glossentry>, processors SHOULD render the <abbreviated-form> element in the following ways:

<table>
<thead>
<tr>
<th>First usage</th>
<th>Render the contents of the &lt;glossSurfaceForm&gt; elements, if it is not empty. If the &lt;glossSurfaceForm&gt; is empty or does not exist, render the contents of the &lt;glossterm&gt; element.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Second and later usage</td>
<td>Render the contents of the &lt;glossAcronym&gt; elements, if it is not empty. If the &lt;glossAcronym&gt; is empty or does not exist, render the contents of the &lt;glossterm&gt; element.</td>
</tr>
</tbody>
</table>

For an example, see the examples in the element-reference topic for the <abbreviated-form> element.

2.2 Localization and the <abbreviated-form> element

Implementations that choose to use the <abbreviated-form> need to consider the effect on translation.

Design of the specialization

The <glossAcronym> and <glossSurfaceForm> elements were designed to accommodate the following realities:

Acronyms do not exist in all languages

An acronym in one language might not have an equivalent in another language. In addition, languages have varying conventions for how an expanded form of a term is displayed. When acronyms are first displayed, some languages will display the expanded form followed by the acronym in parenthesis, while other languages do the reverse. For some acronyms, a translation might need to render both the original and the translated version of the acronym. The <glossSurfaceForm> enables authors and translators to present a locale-appropriate expanded form to the reader.
If a language does not have a acronym for a term, the translation of a glossary entry topic might result in an empty `<glossAcronym>` element.

**Synonyms**

Synonyms are specific to languages, so translation of a glossary entry topic might result in empty `<glossSynonym>` elements.

**Translation quality issues**

The use of `<abbreviated-form>` elements might have a negative effect on the quality and cost of the translation.

- Most translation tools do not resolve key references. Accordingly, translators might need to reference supplementary materials in order to understand the content that they are working with.
- Because many non-English languages vary articles based on gender and case, a simple programmatic insertion of an expanded form or acronym might yield translations that are ungrammatical and awkward.
3 Glossary entry elements

The glossary entry specialization contains markup that supports the development and delivery of glossaries. It also can be used in conjunction with the abbreviated-form domain to provide a solution for rendering different forms of a term on first and later usage in a publication.

3.1 <glossAcronym>

The `<glossAcronym>` element defines an acronym for the term that is specified in the `<glossterm>` element.

Usage information

This element can be used with the `<abbreviated-form>` element to display an expanded version of an acronym the first time that acronym appears in a set of text. See `<abbreviated-form>` for information on how the two elements interact.

Specialization hierarchy

The `<glossAcronym>` element is specialized from `<title>`. It is defined in the glossary entry module.

Attributes

The following attributes are available on this element: ID and conref attributes (29), localization attributes (30), `@base` (30), `@class` (30), `@outputclass` (32), and `@rev` (33).

Example

The following code sample shows how the `<glossAcronym>` element can be used:

```xml
<glossentry id="united-nations">
  <glossterm>United Nations</glossterm>
  <glossdef>The United Nations, referred to informally as the UN, is an intergovernmental organization whose stated purposes are to maintain international peace and security, develop friendly relations among nations, achieve international cooperation, and serve as a center for harmonizing the actions of nations.</glossdef>
  <glossBody>
    <glossSurfaceForm>United Nations (UN)</glossSurfaceForm>
    <glossAlt>
      <glossAcronym>UN</glossAcronym>
    </glossAlt>
  </glossBody>
</glossentry>
```

3.2 <glossAlt>

The `<glossAlt>` element contains information about a variant for the term that is specified in the `<glossterm>` element. A variant might include an acronym or a synonym.

Usage information

The variant should have the same meaning as the term in the `<glossterm>` element; the variant is simply another way to refer to the same term. There might be many ways to refer to a term; each
variant is placed in its own <glossAlt> element. The <glossUsage> element can be used within <glossAlt> to indicate when use of the alternate term is appropriate.

Specialization hierarchy
The <glossAlt> element is specialized from <section>. It is defined in the glossary entry module.

Attributes
The following attributes are available on this element: universal attributes (29).

Example
The following code sample shows how a glossary entry topic might provide alternative forms of the term.

```xml
<glossentry id="usa">
  <glossterm>United States of America</glossterm>
  <glossdef>A federal republic in the northern Western Hemisphere comprising 48 contiguous states, the District of Columbia, Alaska in North America, and Hawaii in the North Pacific, and in some contexts considered along with its five inhabited island territories (Puerto Rico, U.S. Virgin Islands, Guam, North Mariana Islands, American Samoa).</glossdef>
  <glossBody>
    <glossAlt>
      <glossAcronym>US</glossAcronym>
      <glossUsage>Used as an adjective.</glossUsage>
    </glossAlt>
    <glossAlt>
      <glossAcronym>USA</glossAcronym>
      <glossUsage>Used as a noun.</glossUsage>
    </glossAlt>
    <glossAlt>
      <glossSynonym>America</glossSynonym>
      <glossUsage>Do not use; the American continents include other countries.</glossUsage>
    </glossAlt>
  </glossBody>
</glossentry>
```

3.3 <glossBody>
The <glossBody> element contains information about the term that is specified in the <glossterm> element, such as a acronym, synonyms, or usage notes.

Specialization hierarchy
The <glossBody> element is specialized from <conbody>; it is defined in the glossary entry module. The <conbody> element is specialized from <body>; it is defined in the concept module.

Attributes
The following attributes are available on this element: universal attributes (29).

Example
The following code sample shows how the <glossBody> element contains a synonym for the term:

```xml
<glossentry id="sport-drink">
  <glossterm>Sport drink</glossterm>
  <glossdef>A soft drink designed or marketed for consumption in conjunction with sporting activity or strenuous exercise, and which typically contains electrolytes such as sodium, potassium, and
```
chloride, and a high percentage of sugar to restore energy.</glossdef>

3.4 <glossdef>
The <glossdef> element defines the meaning of the term that is specified in the <glossterm> element.

Usage information
If a term has multiple meanings, create a separate <glossentry> topic for each.

Specialization hierarchy
The <glossdef> element is specialized from <abstract>. It is defined in the glossary entry module.

Attributes
The following attributes are available on this element: universal attributes (29).

Example
The following code sample shows the <glossdef> element can be used to define the meaning of the term "raster pattern":

```
<glossentry id="rasterpattern">
  <glossterm>raster pattern</glossterm>
  <glossdef>A series of picture elements (pels) arranged in scan lines to form an image.</glossdef>
</glossentry>
```

3.5 <glossentry>
The <glossentry> element is the top-level element for a topic that defines a glossary term.

Rendering expectations
Because the glossary entry specialization is designed for multiple purposes, it contains elements that typically are not intended to be rendered when a glossary is generated. In addition, when a collection of glossary entry topics is rendered as authoring guidance, generated text might be required for ease of reading. Specialized style sheets and processing are needed to ensure useful output.

Processing expectations
Processing expectations for glossary entry topics are highly implementation-specific and will depend on the output format.

For HTML-based output formats, one possible implementation of glossary entry topics is to generate hyperlinks for <term> element that are associated by key reference with the glossary entry topic. The term definition might be displayed when someone hovers over or clicks on the hyperlink.

For PDF output, one possible implementation of glossary entry topics is to render acronyms or expanded acronyms for <abbreviated-form> elements that are associated by key reference with the glossary
entry topics. The surface form is rendered on first usage, and the acronym is rendered on second or later usage.

Specialization hierarchy
The `<glossentry>` element is specialized from `<concept>`; it is defined in the glossary entry module. The `<concept>` element is specialized from `<topic>`; it is defined in the concept module.

Attributes
The following attributes are available on this element: architectural attributes (34) and universal attributes (29).

For this element, the @id attribute is required.

Example
The following code samples shows how a glossary entry topic provides information about a term that aids in terminology management:

```xml
<glossentry id="usbfd">
  <glossterm>USB flash drive</glossterm>
  <glossdef>A small portable drive.</glossdef>
  <glossUsage>Do not use this term in upper case (for example, in "USB Flash Drive")
    because that suggests a trademark.</glossUsage>
  <glossAlt>
    <glossAcronym>UFD</glossAcronym>
  </glossAlt>
  <glossAlt id="memoryStick">
    <glossSynonym>memory stick</glossSynonym>
    <glossUsage>This is a colloquial term.</glossUsage>
  </glossAlt>
</glossentry>
```

3.6 `<glossSurfaceForm>`

The `<glossSurfaceForm>` element specifies how the term that is specified by the `<glossterm>` element should appear in the text. The surface form is suitable to introduce the term in new contexts or as the first occurrence.

Usage information
The `<glossSurfaceForm>` element is most often used for terms that also specify the `<glossAcronym>` element. In that context, the `<glossSurfaceForm>` element contains the term in a manner that introduces both the term and the acronym, so that later references to the term can be replaced with the acronym alone.

See the `<abbreviated-form>` element for a full description of how the surface form is used together with acronyms.

Specialization hierarchy
The `<glossSurfaceForm>` element is specialized from `<p>`. It is defined in the glossary entry module.

Attributes
The following attributes are available on this element: universal attributes (29).
Example

The following glossary entry topic defines the term "Anti-lock Braking System". Within the topic, the <glossSurfaceForm> element provides a version of the term that combines both the primary term and the acronym. The content of the <glossSurfaceForm> might be rendered in introductory contexts when the glossary entry topic is referenced from an <abbreviated-form> element.

```xml
<glossentry id="abs">
  <glossterm>Anti-lock Braking System</glossterm>
  <glossBody>
    <glossSurfaceForm>Anti-lock Braking System (ABS)</glossSurfaceForm>
    <glossAlt>
      <glossAcronym>ABS</glossAcronym>
    </glossAlt>
  </glossBody>
</glossentry>
```

3.7 <glossSymbol>

The <glossSymbol> element identifies a standard image that is associated with the subject of the term that is specified by <glossterm> element.

Specialization hierarchy

The <glossSymbol> element is specialized from <image>. It is defined in the glossary entry module.

Attributes

The following attributes are available on this element: universal attributes (29), @format (39), @href (39), @keyref (40), @scope (44), and the attributes defined below.

@align

Controls the horizontal alignment of an image when @placement is specified as “break”. Common values include "left", "right", and "center".

@height

Specifies the vertical dimension for the resulting display. The value of this attribute is a real number expressed in decimal notation, optionally followed by a unit of measure. The following units of measurement are supported: cm, em, in, mm, pc, pt, and px (centimeters, ems, inches, millimeters, picas, points, and pixels, respectively). The default unit is px (pixels). Possible values include:"5", "5in", and "10.5cm".

@placement

Indicates whether an image is displayed inline or on a separate line. The default value is inline. Allowable values are "inline", "break", and "-dita-use-conref-target" (46).

@scale

Specifies a percentage as an unsigned integer by which to scale the image in the absence of any specified image height or width; a value of 100 implies that the image should be presented at its intrinsic size. If a value has been specified for the @height or @width attribute (or both), the @scale attribute is ignored.

@scalefit

Specifies whether an image is scaled up or down to fit within available space. The allowable values are "yes", "no", and "-dita-use-conref-target" (46). If @height, @width, or @scale is specified, those attributes determine the graphic size, and the @scalefit attribute is ignored. If none of those attributes are specified and scalefit="yes", then the image is scaled by the same factor in both dimensions, so that the graphic will just fit within the available height or width, whichever is more constraining.
The available width would be that of the prevailing column or table cell, that is, the width a paragraph of text would have if the graphic were a paragraph instead of text. The available height is implementation dependent, but if feasible, it is suggested to be the page or table cell height or some other reasonable value.

@width
Specifies the horizontal dimension for the resulting display. The value of this attribute is a real number expressed in decimal notation, optionally followed by a unit of measure. The following units of measurement are supported: cm, em, in, mm, pc, pt, and px (centimeters, ems, inches, millimeters, picas, points, and pixels, respectively). The default unit is px (pixels). Possible values include: "5", "5in", and "10.5cm".

Example
The following code sample shows how the <glossSymbol> can be used to associate a regional classification icon with the Atlantic puffin:

```xml
<glossentry id="atlanticpuffin">
  <glossterm>Atlantic Puffin</glossterm>
  <glossdef>A sea bird that lives in the Atlantic
  <image href="puffinicon.jpg">
    <alt>Image of an atlantic puffin</alt>
  </image>
  </glossdef>
  <glossBody>
    <glossSymbol href="atlantic.jpg" scope="local">
      <alt>Icon denoting the Atlantic region</alt>
    </glossSymbol>
  </glossBody>
</glossentry>
```

3.8 <glossSynonym>
The <glossSynonym> element provides a term that is a synonym of the term that is specified by the <glossterm> element.

Usage information
The <glossSynonym> element should not be used to specify an acronym; use the <glossAcronym> element for that purpose.

Comment by Kristen James Eberlein on 24 March 2024
Eliot Kimber made the following comment in the (1st) Content Fusion review:

"I think this element is the answer to Dawn's question about <glossAlternateFor> not applying to the entire glossary definition. This element serves that role and, because it allows both <term> and <keyword>, can be a link to the glossary entry of the synonym term.

Do we want to provide an example of this?

Disposition: Unassigned"

Specialization hierarchy
The <glossSynonym> element is specialized from <title>. It is defined in the glossary entry module.
Attributes

The following attributes are available on this element: ID and conref attributes (29), localization attributes (30), @base (30), @class (30), @outputclass (32), and @rev (33).

Example

The following code sample shows how the `<glossSynonym>` element can be used to identify a synonym for the word automobile:

```xml
<glossentry id="automobile">
  <glossterm>Automobile</glossterm>
  <glossdef>A road vehicle, typically with four wheels, powered by an internal combustion engine or an electric motor.</glossdef>
  <glossBody>
    <glossAlt>
      <glossSynonym>car</glossSynonym>
    </glossAlt>
  </glossBody>
</glossentry>
```

3.9 `<glossterm>`

The `<glossterm>` element specifies the term that is defined by the glossary entry topic.

Specialization hierarchy

The `<glossterm>` element is specialized from `<title>`. It is defined in the glossary entry module.

Attributes

The following attributes are available on this element: ID and conref attributes (29), localization attributes (30), @base (30), @class (30), @outputclass (32), and @rev (33).

Example

The following code sample shows how the `<glossterm>` element specifies the term that is defined in the `<glossentry>` topic:

```xml
<glossentry id="css">
  <glossterm>cascading style sheets</glossterm>
  <glossdef>Cascading Style Sheets is a style sheet language that is used for rendering the presentation of a document written in a markup language such as HTML or XML</glossdef>
  <glossBody>
    <glossSurfaceForm>cascading style sheets (CSS)</glossSurfaceForm>
    <glossAlt>
      <glossAcronym>CSS</glossAcronym>
    </glossAlt>
    <glossAlt>
      <glossSynonym>web style sheets</glossSynonym>
    </glossAlt>
  </glossBody>
</glossentry>
```
### 3.10 `<glossUsage>`

The `<glossUsage>` element provides information about how to use the term that is specified in the `<glossterm>` element. It also can be used to provide usage information for acronyms or synonyms.

#### Specialization hierarchy

The `<glossUsage>` element is specialized from `<note>`. It is defined in the glossary entry module.

#### Attributes

The following attributes are available on this element: universal attributes (29) and the attributes defined below.

- **@othertype**
  
  Specifies an alternate note type. This value is used as the user-provided note label when the `@type` attribute value is set to “other”.

- **@type**
  
  Specifies the type of a note. This differs from the `@type` attribute on many other DITA elements. The following are the allowable values:

  - "attention"
  - "caution"
  - "danger"
  - "important"
  - "note"
  - "notice"
  - "other"
  - "remember"
  - "restriction"
  - "tip"
  - "trouble"
  - "warning"
  - "-dita-use-conref-target"

#### Example

The following code sample shows how the `<glossUsage>` element is used to provide additional information about possible variants for the term "soft drink."

```xml
<glossentry id="softdrink">
  <glossterm>soft drink</glossterm>
  <glossdef>A nonalcoholic drink, especially one that is carbonated.</glossdef>
  <glossBody>
    <glossAlt>
      <glossSynonym>pop</glossSynonym>
      <glossUsage>Used primarily in the North and Midwest</glossUsage>
    </glossAlt>
    <glossAlt>
      <glossSynonym>soda</glossSynonym>
      <glossUsage>Used primarily in the West and Northeast</glossUsage>
    </glossAlt>
    <glossAlt>
      <glossSynonym>Coke</glossSynonym>
      <glossUsage>Used primarily in the South</glossUsage>
    </glossAlt>
  </glossBody>
</glossentry>
```
A Aggregated RFC-2119 statements

This appendix contains all the normative statements from the DITA for Technical Content 2.0 specification. They are aggregated here for convenience in this non-normative appendix.
B Attributes

This section contains definitions for commonly-used attributes. If an attribute is defined differently on a specific element, that information is covered in the topic for the specific element.

Comment by Kristen J Eberlein on 29 December 2021
Add a brief overview of the fact that some specific attributes are overloaded – and have different meanings depending on what element they are specified upon.
Disposition: Unassigned

B.1 Attribute groups

Many of the attributes used on DITA elements are defined in attribute groups. These attribute groups are used both in the grammar files and the specification.

Architectural attributes

This group contains a set of attributes that are defined for document-level elements such as <topic> and <map>.

@DITAArchVersion (architectural attributes)
Specifies the version of the DITA architecture that is in use. This attribute is in the namespace http://dita.oasis-open.org/architecture/2005/. This attribute is specified in the topic and map modules, and it uses a default value of the current version of DITA. The current default is "2.0".

@specializations (architectural attributes)
Specifies the attribute-domain specializations that are included in the document-type shell. This attribute is set as a default within the document-type shell. The value varies depending on what domains are integrated into the document-type shell. For example, a grammar file that includes the specialized attributes @audience, @deliveryTarget, and @newBaseAtt would set the value to @props/audience @props/deliveryTarget @base/newBaseAtt.

@xmlns:ditaarch (architectural attributes)
Declares the default DITA namespace. This namespace is declared as such in the RNG modules for <topic> and <map>, but it is specified as an attribute in the equivalent DTD-based modules. The value is fixed to "http://dita.oasis-open.org/architecture/2005/".

Common map attributes

This group contains attributes that are frequently used on map elements.

Comment by Kristen J Eberlein on 28 September 2022
I've added draft comments to the attribute definitions in this section that explain how the attribute is defined in the "DITA map attributes" topic.
Disposition: Unassigned

@cascade (common map attributes)
Specifies how metadata attributes cascade within a map. The specification defines the following values:
merge
Indicates that the metadata attributes cascade, and that the values of the metadata attributes are additive. This is the processing default for the @cascade attribute.

nomerge
Indicates that the metadata attributes cascade, but that they are not additive for <topicref> elements that specify a different value for a specific metadata attribute. If the cascading value for an attribute is already merged based on multiple ancestor elements, that merged value continues to cascade until a new value is encountered. That is, setting cascade="nomerge" does not undo merging that took place on ancestor elements.

Processors can also define custom, implementation-specific tokens for this attribute.

See Cascading of metadata attributes in a DITA map for more information about how this attribute interacts with metadata attributes.

@chunk (common map attributes)
Specifies how a processor should render a map or branch of a map. For example, it can be used to specify that individual topic documents should be rendered as a single document, or that a single document with multiple topics should be rendered as multiple documents.

The following values are valid:

combine
Instructs a processor to combine the referenced source documents for rendering purposes. This is intended for cases where a publishing process normally results in a single output artifact for each source XML document.

split
Instructs a processor to split each topic from the referenced source document into its own document for rendering purposes. This is intended for cases where a publishing process normally results in a single output artifact for each source XML document, regardless of how many DITA topics exist within each source document.

Processors can also define custom, implementation-specific tokens for this attribute.

For a detailed description of the @chunk attribute and its usage, see Chunking.

@collection-type (common map attributes)
Specifies how topics or links relate to each other. The processing default is "unordered", although no default is specified in the OASIS-provided grammar files. The following values are valid:

unordered
Indicates that the order of the child topics is not significant.

sequence
Indicates that the order of the child topics is significant. Output processors will typically link between them in order.

choice
Indicates that one of the children should be selected.

family
Indicates a tight grouping in which each of the referenced topics not only relates to the current topic but also relate to each other.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@collection-type
The @collection-type attribute specifies how the children of a <topicref> element relate to their parent and to each other. This attribute, which is set on the parent element,
typically is used by processors to determine how to generate navigation links in the rendered topics. For example, a `@collection-type` value of "sequence" indicates that children of the specifying `<topicref>` element represent an ordered sequence of topics; processors might add numbers to the list of child topics or generate next/previous links for online presentation. This attribute is available in topics on the `<linklist>` and `<linkpool>` elements, where it has the same behavior. Where the `@collection-type` attribute is available on elements that cannot directly contain elements, the behavior of the attribute is undefined.

Disposition: Unassigned

Comment by Kristen J Eberlein on 28 September 2022

In the definitions of the supported values, do we want to refer to "resources" instead of "topics"? Since we specify that `@collection-type` specifies "how topics or links relate to each other" ...

Disposition: Unassigned

@`keyscope` (common map attributes)

Specifies that the element marks the boundaries of a key scope.

See B.4 STUB CONTENT (46) for information on using this attribute.

Comment by Kristen J Eberlein on 28 September 2022

Here is the content from the "DITA map attributes" topic:

@`keyscope`

Defines a new scope for key definition and resolution, and gives the scope one or more names. For more information about key scopes, see Indirect key-based addressing.

Disposition: Unassigned

@`linking` (common map attributes)

Specifies linking characteristics of a topic specific to the location of this reference in a map. If the value is not specified locally, the value might cascade from another element in the map (for cascade rules, see Cascading of metadata attributes in a DITA map).

Comment by robander on Dec 28 2021

The text below matches 1.3 spec text but I'm nervous about "cannot link" type definition. It's describing how to generate links based on the current context in the map - it's not describing what the topic itself is allowed to link to, which is how I interpret "can".

Disposition: Unassigned

The following values are valid:

- `targetonly`
  A topic can only be linked to and cannot link to other topics.

- `sourceonly`
  A topic cannot be linked to but can link to other topics.

- `normal`
  A topic can be linked to and can link to other topics. Use this to override the linking value of a parent topic.

- `none`
  A topic cannot be linked to or link to other topics.
Comment by Kristen J Eberlein on 28 September 2022

Here is the content from the "DITA map attributes" topic:

@linking

By default, the relationships between the topics that are referenced in a map are reciprocal:

- Child topics link to parent topics and vice versa.
- Next and previous topics in a sequence link to each other.
- Topics in a family link to their sibling topics.
- Topics referenced in the table cells of the same row in a relationship table link to each other. A topic referenced within a table cell does not (by default) link to other topics referenced in the same table cell.

This behavior can be modified by using the @linking attribute, which enables an author or information architect to specify how a topic participates in a relationship. The following values are valid:

- linking="none"
  Specifies that the topic does not exist in the map for the purposes of calculating links.
- linking="sourceonly"
  Specifies that the topic will link to its related topics but not vice versa.
- linking="targetonly"
  Specifies that the related topics will link to it but not vice versa.
- linking="normal"
  Default value. It specifies that linking will be reciprocal (the topic will link to related topics, and they will link back to it).

Authors also can create links directly in a topic by using the <xref> or <link> elements, but in most cases map-based linking is preferable, because links in topics create dependencies between topics that can hinder reuse.

Note that while the relationships between the topics that are referenced in a map are reciprocal, the relationships merely imply reciprocal links in generated output that includes links. The rendered navigation links are a function of the presentation style that is determined by the processor.

Disposition: Unassigned

@processing-role (common map attributes)
Specifies whether the referenced resource is processed normally or treated as a resource that is only included in order to resolve references, such as key or content references. The following values are valid:

- normal
  Indicates that the resource is a readable part of the information set. It is included in navigation and search results. This is the default value for the <topicref> element.

- resource-only
  Indicates that the resource should be used only for processing purposes. It is not included in navigation or search results, nor is it rendered as a topic. This is the default value for the <keydef> element.

@dita-use-conref-target
See Using the @dita-use-conref-target value for more information.
If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

@search (common map attributes)
Specifies whether the target is available for searching. If the value is not specified locally, the value might cascade from another element in the map (for cascade rules, see Cascading of metadata attributes in a DITA map). The following values are valid: “yes”, “no”, and “-dita-use-conref-target”.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@search
   Specifies whether the topic is included in search indexes.
Disposition: Unassigned

@subjectrefs (common map attributes)
Specifies one or more keys that are each defined by a subject definition in a subject scheme map. Multiple values are separated by white space.

@toc (common map attributes)
Specifies whether a topic appears in the table of contents (TOC) based on the current map context. If the value is not specified locally, the value might cascade from another element in the map (for cascade rules, see Cascading of metadata attributes in a DITA map). The following values are valid:

yes
   The topic appears in a generated TOC.

no
   The topic does not appear in a generated TOC.

-dita-use-conref-target
   See B.4 STUB CONTENT (46) for more information.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@toc
   Specifies whether topics are excluded from navigation output, such as a Web site map or an online table of contents. By default, <topicref> hierarchies are included in navigation output; relationship tables are excluded.

Disposition: Unassigned

Complex table attributes
This group includes attributes that are defined on complex table elements. Unless other noted, these attributes are part of the OASIS Exchange Table Model. Complex table elements typically use only a subset of the attributes that are defined in this group.

@align (complex table attributes)
Specifies the horizontal alignment of text in table entries. The following values are valid:

left
   Indicates left alignment of the text.

right
   Indicates right alignment of the text.
center
Indicates center alignment of the text.

justify
Justifies the contents to both the left and the right.

char
Indicates character alignment. The text is aligned with the first occurrence of the character specified by the @char attribute.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

The @align attribute is available on the following table elements: <colspec>, <entry>, and <tgroup>.

@char (complex table attributes)
Specifies the alignment character, which is the character that is used for aligning the text in table entries. This attribute applies when align="char". A value of "" (the null string) means there is no aligning character.

For example, if align="char" and char="." are specified, then text in the table entry aligns with the first occurrence of the period within the entry. This might be useful if decimal alignment is required.

The @char attribute is available on the following table elements: <colspec> and <entry>.

@charoff (complex table attributes)
Specifies the horizontal offset of the alignment character that is specified by the @char attribute. The value is a greater-than-zero number that is less than or equal to 100. It represents the percentage of the current column width by which the text is offset to the left of the alignment character.

For example, if align="char", char=".", and charoff="50" are all specified, then text in the table entry is aligned 50% of the distance to the left of the first occurrence of the period character within the table entry.

The @charoff attribute is available on the following table elements: <colspec> and <entry>.

@colsep (complex table attributes)
Specifies whether to render column separators between table entries. The following values are valid: "0" (no separators) and "1" (separators).

The @colsep attribute is available on the following table elements: <colspec>, <entry>, <table>, and <tgroup>.

@rowheader (complex table attributes)
Specifies whether the entries in the respective column are row headers. The following values are valid:

firstcol
Indicates that entries in the first column of the table are row headers. This applies when the @rowheader attribute is specified on the <table> element.

headers
Indicates that entries of the column that is described using the <colspec> element are row headers. This applies when the @rowheader attribute is specified on the <colspec> element.

norowheader
Indicates that entries in the first column are not row headers. This applies when the @rowheader attribute is specified on the <table> element.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.
Note  This attribute is not part of the OASIS Exchange Table Model upon which DITA tables are based. Some processors or output formats might not support all values.

The @rowheader attribute is available on the following table elements: <table> and <colspec>.

@rowsep (complex table attributes)
Specifies whether to render row separators between table entries. The following values are valid: "0" (no separators) and "1" (separators).

The @rowsep attribute is available on the following table elements: <colspec>, <entry>, <row>, <table>, and <tgroup>.

@valign (complex table attributes)
Specifies the vertical alignment of text in table entries. The following values are valid:
bottom  Indicates that text is aligned with the bottom of the table entry.
middle  Indicates that text is aligned with the middle of the table entry.
top  Indicates that text is aligned with the top of the table entry.

-dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

The @valign attribute is available on the following table elements: <entry>, <tbody>, <thead>, and <row>.

Data-element attributes
This group contains attributes that are defined on the <data> element and its specializations.

@datatype (data-element attributes)
Specifies the type of data contained in the @value attribute or within the <data> element. A typical use of @datatype will be the identifying URI for an XML Schema datatype.

@name (data-element attributes)
Defines a unique name for the object.

Comment by robander
Do we need to specify the scope of "unique" here?
Disposition: Unassigned

@value (data-element attributes)
Specifies a value associated with the current property or element.

Date attributes
This group contains attributes that take date values. They are defined on metadata elements that work with date information:

@expiry (date attributes)
Specifies the date when the information should be retired or refreshed. The date is specified using the ISO 8601 format: YYYY-MM-DD, where YYYY is the year, MM is the month (01 to 12), and DD is the day (01-31).

@golive (date attributes)
Specifies the publication or general availability (GA) date. The date is specified using the ISO 8601 format: YYYY-MM-DD, where YYYY is the year, MM is the month (01 to 12), and DD is the day (01-31).
Display attributes

This group contains attributes that affect the rendering of many elements.

@expanse (display attributes)
Specifies the horizontal placement of the element. The following values are valid:
- column
  Indicates that the element is aligned with the current column margin.
- page
  Indicates that the element is placed on the left page margin for left-to-right presentation or the
  right page margin for right-to-left presentation.
- spread
  Indicates that the object is rendered across a multi-page spread. If the output format does not
  have anything that corresponds to spreads, then "spread" has the same meaning as "page".
- textline
  Indicates that the element is aligned with the left (for left-to-right presentation) or right (for right-
  to-left presentation) margin of the current text line and takes indentation into account.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

For <table>, in place of the @expanse attribute that is used by other DITA elements, the @pgwide
attribute is used in order to conform to the OASIS Exchange Table Model.

Some processors or output formats might not support all values.

@frame (display attributes)
Specifies which portion of a border surrounds the element. The following values are valid:
- all
  Indicates that a line is rendered at the top, bottom, left, and right of the containing element.
- bottom
  Indicates that a line is rendered at the bottom of the containing element.
- none
  Indicates that no lines are rendered.
- sides
  Indicates that a line is rendered at the left and right of the containing element.
- top
  Indicates that a line is rendered at the top of the containing element.
- topbot
  Indicates that a line is rendered at the top and bottom of the containing element.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

Some processors or output formats might not support all values.

@scale (display attributes)
Specifies the percentage by which fonts are resized in relation to the normal text size. The value of
this attribute is a positive integer. When used on <table> or <simpletable>, the following values
are valid: "50", "60", "70", "80", "90", "100", "110", "120", "130", "140", "160", "180", "200", and -dita-use-
conref-target (46).

This attribute is primarily useful for print-oriented display. Some processors might not support all
values.

If the @scale attribute is specified on an element that contains an image, the image is not scaled.
The image is scaled only if a scaling property is explicitly specified for the <image> element.
**ID and conref attributes**

This group contains the attributes that enable the naming and referencing of elements.

@conaction

Specifies how the element content will be pushed into a new location. The following values are valid:

- **mark**
  The element acts as a marker when pushing content before or after the target, to help ensure that the push action is valid. The element with conaction="mark" also specifies the target of the push action with @conref. Content inside of the element with conaction="mark" is not pushed to the new location.

- **pushafter**
  Content from this element is pushed after the location specified by @conref on the element with conaction="mark". The element with conaction="pushafter" is the first sibling element after the element with conaction="mark".

- **pushbefore**
  Content from this element is pushed before the location specified by @conref on the element with conaction="mark". The element with conaction="pushbefore" is the first sibling element before the element with conaction="mark".

- **pushreplace**
  Content from this element replaces any content from the element referenced by the @conref attribute. A second element with conaction="mark" is not used when using conaction="pushreplace".

- **-dita-use-conref-target**
  See Using the -dita-use-conref-target value for more information.

See [B.4 STUB CONTENT](46) for examples and details about the syntax.

@conkeyref

Specifies a key name or a key name with an element ID that acts as an indirect reference to reusable content. The referenced content is used in place of the content of the current element. See [B.4 STUB CONTENT](46) for more details about the syntax and behaviors.

@conref

Specifies a URI that references a DITA element. The referenced content is used in place of the content of the current element. See [B.4 STUB CONTENT](46) for examples and details about the syntax.

@conre fend

Specifies a URI that references the last element in a sequence of elements, with the first element of the sequence specified by @conref. The referenced sequence of elements is used in place of the content of the current element. See [B.4 STUB CONTENT](46) for examples and details about the syntax.

@id

Specifies an identifier for the current element. This ID is the target for references by @href and @conref attributes and for external applications that refer to DITA or LwDITA content. This attribute is defined with the XML data type NMTOKEN, except where noted for specific elements within the language reference.

See [id attribute](46) for more details.

**Inclusion attributes**

This group includes attributes defined on `<include>` and its specializations:
@encoding (inclusion attributes)

Comment by Kristen J Eberlein on 29 April 2019
Can we replace "should" in the following definition?
Disposition: Unassigned

Specifies the character encoding to use when translating the character data from the referenced content. The value should be a valid encoding name. If not specified, processors may make attempts to automatically determine the correct encoding, for example using HTTP headers, through analysis of the binary structure of the referenced data, or the <?xml?> processing instruction when including XML as text. The resource should be treated as UTF-8 if no other encoding information can be determined.

When parse="xml", standard XML parsing rules apply for the detection of character encoding. The necessity and uses of @encoding for non-standard values of @parse are implementation-dependent.

@parse (inclusion attributes)

Specifies the processing expectations for the referenced resource. Processors must support the following values:

- text
  The contents should be treated as plain text. Reserved XML characters should be displayed, and not interpreted as XML markup.

- xml
  The contents of the referenced resource should be treated as an XML document, and the referenced element should be inserted at the location of the <include> element. If a fragment identifier is included in the address of the content, processors must select the element with the specified ID. If no fragment identifier is included, the root element of the referenced XML document is selected. Any grammar processing should be performed during resolution, such that default attribute values are explicitly populated. Prolog content must be discarded.

  It is an error to use parse="xml" anywhere other than within <foreign> or a specialization thereof.

  Processors may support other values for the @parse attribute with proprietary processing semantics. Processors should issue warnings and use <fallback> when they encounter unsupported @parse values. Non-standard @parse instructions should be expressed as URIs.

  **Note** Proprietary @parse values will likely limit the portability and interoperability of DITA content, so should be used with care.

Link relationship attributes

This group contains attributes whose values can be used for representing navigational relationships.

@format (link-relationship attributes)

Specifies the format of the resource that is referenced. See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.
@href (link-relationship attributes)
Specifies a reference to a resource. See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

@scope (link-relationship attributes)
Specifies the closeness of the relationship between the current document and the referenced resource. The following values are valid: "local", "peer", "external", and "-dita-use-conref-target".
See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

@type (link-relationship attributes)
Describes the target of a reference. See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

Localization attributes

Comment by Kristen J Eberlein on 29 September 2022
The definition of the localizations attribute matches how they are described in the architectural topics. Wherever possible, the definition is reused. Where it is not reused (because the definition in the archSpec topics is in a shortdesc), I've checked to ensure that wording is identical.

Disposition: Unassigned

This group contains the attributes that are related to translation and localization.

@dir
Identifies or overrides the text directionality. The following values are valid:

lro
Indicates an override of the Unicode Bidirectional Algorithm, forcing the element into left-to-right mode.

ltr
Indicates left-to-right.

rlo
Indicates an override of the Unicode Bidirectional Algorithm, forcing the element into right-to-left mode.

rtl
Indicates right-to-left.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

See The dir attribute for more information.

@translate
Specifies whether the content of the element should be translated. The following values are valid: "yes", "no", and "-dita-use-conref-target".

See Element-by-element recommendations for translators for suggested processing defaults for each element.

Comment by Kristen J Eberlein on 31 December 2021
Does Element-by-element recommendations for translators really provide suggested processing defaults for each element? I thought it covered whether an element was block or in-line and whether there were considerations that translators needed to be aware of.
@xml:lang
Specifies the language and optional locale of the content that is contained in an element. Valid values are language tokens or the null string. The @xml:lang attribute and its values are described in the Extensible Markup Language 1.0 specification, fifth edition.

Comment by Kristen J Eberlein on 29 September 2022
Do we also want to direct readers to the architectural topics about the @xml:lang attribute?

Disposition: Unassigned

Metadata attributes
This group contains common metadata attributes: @base, @importance, @props, @rev, and @status. The @base and @props attributes can be specialized.

@base
Specifies metadata about the element. It is often used as a base for specialized attributes that have a simple syntax for values, but which are not conditional processing attributes.

The @base attribute takes a space-delimited set of values. However, when serving as a container for generalized attributes, the attribute values will be more complex. See Attribute generalization for more details.

@importance
Specifies the importance or priority that is assigned to an element. The following values are valid: "default", "deprecated", "high", "low", "normal", "obsolete", "optional", "recommended", "required", "urgent", and "-dita-use-conref-target". This attribute is not used for conditional processing, although applications might use the value of the @importance attribute to highlight elements. For example, in steps of a task topic, the value of the @importance attribute indicates whether a step is optional or required.

Comment by Kristen J Eberlein on 29 September 2022
I think the phrase “to highlight elements” is a little off. Maybe "render generated text"? And how about adding "Processors often add text or images to ensure that readers of the generated content understand whether the step is optional or required.” to the end of the example?

Disposition: Unassigned

@props
Specifies metadata about the element. New attributes can be specialized from the @props attribute. This attribute supports conditional processing. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

The @props attribute takes a space-delimited set of values. However, when serving as a container for generalized attributes, the attribute values will be more complex. See Attribute generalization for more details.

@rev
Specifies a revision level of an element that identifies when the element was added or modified. It can be used to flag outputs when it matches a run-time parameter. It cannot be used for filtering nor is it sufficient to be used for version control. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.
Comment by Kristen J Eberlein on 29 September 2022

I want to tweak this. How about the following? Also, neither definition describes what values are permitted.

Specifies metadata that identifies when the element was added or the content of the element was modified. The @rev attribute can be used for flagging. It cannot be used for filtering nor is it sufficient to be used for version control. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

Disposition: Unassigned

@status
 specifies the modification status of the element. The following values are valid: “new”, “changed”, “deleted”, “unchanged”, and “-dita-use-conref-target”.

Simple table attributes

This group includes attributes that are defined only on the <simpletable> element: @keycol and @relcolwidth. These attributes are listed in a group because the <simpletable> element is frequently used as a specialization base.

@keycol (simpletable attributes)
 specifies the column that contains the content that represents the key to the tabular structure. If @keycol is present and assigned a numerical value, the specified column is treated as a vertical header.

@relcolwidth (simpletable attributes)
 specifies the width of each column in relationship to the width of the other columns. The value is a space-separated list of relative column widths. Each column width is specified as a positive integer or decimal number followed by an asterisk character.

For example, the value relcolwidth="1* 2* 3*" gives a total of 6 units across three columns. The relative widths are 1/6, 2/6, and 3/6 (16.7%, 33.3%, and 50%). Similarly, the value relcolwidth="90* 150*" causes relative widths of 90/240 and 150/240 (37.5% and 62.5%).

Table accessibility attributes

This group defines a set of attributes that promote table accessibility:

@headers
 specifies which entries in the current table provide headers for this cell. The @headers attribute contains an unordered set of unique, space-separated tokens, each of which is an ID reference of an entry from the same table.

@scope
 specifies that the current entry is a header for other table entries. The following values are valid:

  col
  indicates that the current entry is a header for all cells in the column.

  colgroup
  indicates that the current entry is a header for all cells in the columns that are spanned by this entry.

  row
  indicates that the current entry is a header for all cells in the row.
Universal attributes

This group defines a set of attributes that are available on almost all DITA elements. It includes all elements in the ID, localization, and metadata attribute groups, as well as the following attributes:

@class **(not for use by authors)**

*This attribute is not for use by authors. If an editor displays @class attribute values, do not edit them.* Specifies a default value that defines the specialization ancestry of the element. Its predefined values allow DITA tools to work correctly with specialized elements. In a generalized DITA document the @class attribute value in the generalized instance might differ from the default value for the @class attribute for the element as given in the DTD or schema. See The class attribute rules and syntax for more information. This attribute is specified on every element except for the <dita> container element. It is always specified with a default value, which varies for each element.

@outputclass

Specifies a role that the element is playing. The role must be consistent with the basic semantic and expectations for the element. In particular, the @outputclass attribute can be used for styling during output processing; HTML output will typically preserve @outputclass for CSS processing.

Comment by robander

I don't like "The role must be consistent...", that seems like best practice that cannot be normative – and I could easily say outputclass="flashy" which makes my element show up with sparkles, and has nothing to do with "the basic semantic and expectations for the element".

Disposition: Unassigned

B.2 Universal attribute group

The universal attribute group defines a set of common attributes that are available on almost every DITA element. The universal attribute group includes all attributes from the ID, localization, and metadata attribute groups, plus the @class and @outputclass attributes.

Comment by Kristen J Eberlein on 29 December 2021

This is something wrong with the organizational structure of this topic ... Look at it in outline form, and check that the sections, titles, and content all make logical sense with the topic title of "Universal attribute group".

Disposition: Unassigned

Common attribute groups

The following attribute groups are referenced in this specification. They are also used in the grammar files when the element attributes are defined.

Universal attributes

Includes @class and @outputclass, along with every attribute in the ID, localization, and metadata attribute groups.

ID attributes

This group includes the attributes that enable the naming and referencing of elements: @conaction, @conkeyref, @conref, @conrefend, and @id.
Localization attributes
This group includes attributes that are related to translation and localization: @dir, @translate, and @xml:lang.

Metadata attributes

Comment by Kristen J Eberlein on 31 December 2021
Why do we need to mention that two attributes are available for specialization here? I think it makes the paragraph hard to read.
Disposition: Unassigned

This group includes common metadata attributes, two of which are available for specialization: @base, @importance, @props, @rev, and @status.

The base DITA vocabulary from OASIS includes several specializations of @props: @audience, @deliveryTarget, @otherprops, @platform, and @product. These attributes are defined as attribute-extension domains. By default, they are integrated into all OASIS-provided document-type shells, but they can be made unavailable by implementing custom document-type shells.

Comment by Kristen J Eberlein on 29 December 2021
Why do we provide information about specialization and custom document-type shells here? I think that information could be removed.
Disposition: Unassigned

Universal attribute definitions
The universal attributes for OASIS DITA elements are defined below. Specialized attributes, which are part of the OASIS distribution but are only available when explicitly included in a shell, are noted in the list.

@audience (specialized attribute)
Indicates the intended audience for the element. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

@base
Specifies metadata about the element. It is often used as a base for specialized attributes that have a simple syntax for values, but which are not conditional processing attributes.

The @base attribute takes a space-delimited set of values. However, when serving as a container for generalized attributes, the attribute values will be more complex. See Attribute generalization for more details.

@class (not for use by authors)
This attribute is not for use by authors. If an editor displays @class attribute values, do not edit them. Specifies a default value that defines the specialization ancestry of the element. Its predefined values allow DITA tools to work correctly with specialized elements. In a generalized DITA document the @class attribute value in the generalized instance might differ from the default value for the @class attribute for the element as given in the DTD or schema. See The class attribute rules and syntax for more information. This attribute is specified on every element except for the <dita> container element. It is always specified with a default value, which varies for each element.

@conaction
Specifies how the element content will be pushed into a new location. The following values are valid:
mark
  The element acts as a marker when pushing content before or after the target, to help ensure
  that the push action is valid. The element with conaction="mark" also specifies the target of
  the push action with @conref. Content inside of the element with conaction="mark" is not
  pushed to the new location.

pushafter
  Content from this element is pushed after the location specified by @conref on the element with
  conaction="mark". The element with conaction="pushafter" is the first sibling element
  after the element with conaction="mark".

pushbefore
  Content from this element is pushed before the location specified by @conref on the element
  with conaction="mark". The element with conaction="pushbefore" is the first sibling
  element before the element with conaction="mark".

pushreplace
  Content from this element replaces any content from the element referenced by the
  @conref attribute. A second element with conaction="mark" is not used when using
  conaction="pushreplace".

@dita-use-conref-target
  See Using the -dita-use-conref-target value for more information.

See B.4 STUB CONTENT (46) for examples and details about the syntax.

@conkeyref
  Specifies a key name or a key name with an element ID that acts as an indirect reference to reusable
  content. The referenced content is used in place of the content of the current element. See B.4 STUB
  CONTENT (46) for more details about the syntax and behaviors.

@conref
  Specifies a URI that references a DITA element. The referenced content is used in place of the
  content of the current element. See B.4 STUB CONTENT (46) for examples and details about the
  syntax.

@conrefend
  Specifies a URI that references the last element in a sequence of elements, with the first element of
  the sequence specified by @conref. The referenced sequence of elements is used in place of the
  content of the current element. See B.4 STUB CONTENT (46) for examples and details about the
  syntax.

@deliveryTarget (specialized attribute)
  Specifies the intended delivery target of the content, for example, "html", "pdf", or "epub". If no value
  is specified but the attribute is specified on a containing element within a map or within the related-
  links section, the value cascades from the closest containing element.

@dir
  Identifies or overrides the text directionality. The following values are valid:

  lro
    Indicates an override of the Unicode Bidirectional Algorithm, forcing the element into left-to-right
    mode.

  ltr
    Indicates left-to-right.

  rlo
    Indicates an override of the Unicode Bidirectional Algorithm, forcing the element into right-to-left
    mode.

  rtl
    Indicates right-to-left.
-dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

See The dir attribute for more information.

@id
Specifies an identifier for the current element. This ID is the target for references by @href and @conref attributes and for external applications that refer to DITA or LwDITA content. This attribute is defined with the XML data type NMTOKEN, except where noted for specific elements within the language reference.

See id attribute for more details.

@importance
Specifies the importance or priority that is assigned to an element. The following values are valid: "default", "deprecated", "high", "low", "normal", "obsolete", "optional", "recommended", "required", "urgent", and "-dita-use-conref-target". This attribute is not used for conditional processing, although applications might use the value of the @importance attribute to highlight elements. For example, in steps of a task topic, the value of the @importance attribute indicates whether a step is optional or required.

Comment by Kristen J Eberlein on 29 September 2022
I think the phrase “to highlight elements” is a little off. Maybe "render generated text"? And how about adding "Processors often add text or images to ensure that readers of the generated content understand whether the step is optional or required.” to the end of the example?

Disposition: Unassigned

@otherprops (specialized attribute)
Specifies a property or properties that provide selection criteria for the element. Alternatively, the @props attribute can be specialized to provide a new metadata attribute instead of using the general @otherprops attribute. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

@outputclass
Specifies a role that the element is playing. The role must be consistent with the basic semantic and expectations for the element. In particular, the @outputclass attribute can be used for styling during output processing; HTML output will typically preserve @outputclass for CSS processing.

Comment by robander
I don't like "The role must be consistent...", that seems like best practice that cannot be normative – and I could easily say outputclass="flashy" which makes my element show up with sparkles, and has nothing to do with "the basic semantic and expectations for the element".

Disposition: Unassigned

@platform (specialized attribute)
Indicates operating system and hardware. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

Comment by robander
I think this could specify a platform that is not an operating system or hardware, right? The current definition explicitly limits platform to those two … maybe "Specifies a platform or platforms to which the element applies, such as the operating system or hardware relevant to a task.”

Disposition: Unassigned
@product (specialized attribute)
Specifies the name of the product to which the element applies. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

@props
Specifies metadata about the element. New attributes can be specialized from the @props attribute. This attribute supports conditional processing. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

The @props attribute takes a space-delimited set of values. However, when serving as a container for generalized attributes, the attribute values will be more complex. See Attribute generalization for more details.

@rev
Specifies a revision level of an element that identifies when the element was added or modified. It can be used to flag outputs when it matches a run-time parameter. It cannot be used for filtering nor is it sufficient to be used for version control. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

Comment by Kristen J Eberlein on 29 September 2022
I want to tweak this. How about the following? Also, neither definition describes what values are permitted.

Specifies metadata that identifies when the element was added or the content of the element was modified. The @rev attribute can be used for flagging. It cannot be used for filtering nor is it sufficient to be used for version control. If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

Disposition: Unassigned

@status
Specifies the modification status of the element. The following values are valid: "new", "changed", "deleted", "unchanged", and "-dita-use-conref-target".

@translate
Specifies whether the content of the element should be translated. The following values are valid: "yes", "no", and "-dita-use-conref-target".

See Element-by-element recommendations for translators for suggested processing defaults for each element.

Comment by Kristen J Eberlein on 31 December 2021
Does Element-by-element recommendations for translators really provide suggested processing defaults for each element? I thought it covered whether an element was block or in-line and whether there were considerations that translators needed to be aware of.

Disposition: Unassigned

@xml:lang
Specifies the language and optional locale of the content that is contained in an element. Valid values are language tokens or the null string. The @xml:lang attribute and its values are described in the Extensible Markup Language 1.0 specification, fifth edition.
B.3 Common attributes

The common attributes topic collects defines most of the attributes that are used on more than one base element.

Common attribute groups

The following groups are referenced in this specification, and they are also used in grammar files when defining attributes for elements.

Architectural attributes

This group includes a set of attributes that are defined for document-level elements such as <topic> and <map>: @DITAArchVersion, @specializations, and @xmlns:ditaarch.

Common map attributes

This group includes attributes that are frequently used on map elements: @cascade, @chunk, @collection-type, @keyscope, @linking, @processing-role, @search, @toc, and @subjectrefs.

Complex table attributes

This group includes attributes that are defined on table elements but not simple table elements. These attributes are part of the OASIS Exchange Table Model, unless otherwise noted. Table elements generally use only a subset of the attributes that are defined in this group. This group contains the following attributes: @align, @char, @charoff, @colsep, @rowheader, @rowsep, and @valign.

Data-element attributes

Includes attributes defined on <data> and its many specializations: @datatype, @name, and @value

Date attributes

Includes attributes that take date values, and are defined on metadata elements that work with date information: @expiry and @golive

Display attributes

This group includes attributes that affect the rendering of many elements: @expanse, @frame, and @scale.

Inclusion attributes

Includes attributes defined on <include> and its specializations: @encoding and @parse.

Link-relationship attributes

This group includes attributes whose values can be used for representing navigational relationships: @format, @href, @type, and @scope.

Simple table attributes

Comment by Kristen J Eberlein on 29 December 2021

If I have jumped to this place in a document from the element-reference topic, I want the attributes listed here in the “Simple table group” to be hyperlinked to the actual definition.
This group includes attributes that are defined only on the `<simpletable>` element: `@keycol` and `@relcolwidth`. These attributes are listed in a group because the `<simpletable>` element is frequently used as a specialization base.

**Table accessibility attributes**

This group contains attributes that are defined on the `<stentry>` element and its specializations: `@headers` (39) and `@scope (as defined on `<stentry>`)` (44).

**Other attributes (not in a group)**

These are attributes that are used in the same way on more than one base element, but they are not formally grouped together: `@compact`, `@duplicates`, `@impose-role`, `@otherrole`, `@role`, and `@title-role`.

**Common attribute definitions**

Common attributes, including those in the groups listed above, are defined as follows.

**@align (complex table attributes)**

 Specifies the horizontal alignment of text in table entries. The following values are valid:

- **left**
  Indicates left alignment of the text.

- **right**
  Indicates right alignment of the text.

- **center**
  Indicates center alignment of the text.

- **justify**
  Justifies the contents to both the left and the right.

- **char**
  Indicates character alignment. The text is aligned with the first occurrence of the character specified by the `@char` attribute.

- **-dita-use-conref-target**
  See Using the `-dita-use-conref-target` value for more information.

The `@align` attribute is available on the following table elements: `<colspec>`, `<entry>`, and `<tgroup>`.

**@cascade (common map attributes)**

 Specifies how metadata attributes cascade within a map. The specification defines the following values:

- **merge**
  Indicates that the metadata attributes cascade, and that the values of the metadata attributes are additive. This is the processing default for the `@cascade` attribute.

- **nomerge**
  Indicates that the metadata attributes cascade, but that they are not additive for `<topicref>` elements that specify a different value for a specific metadata attribute. If the cascading value for an attribute is already merged based on multiple ancestor elements, that merged value continues to cascade until a new value is encountered. That is, setting `cascade="nomerge"` does not undo merging that took place on ancestor elements.
Processors can also define custom, implementation-specific tokens for this attribute. See Cascading of metadata attributes in a DITA map for more information about how this attribute interacts with metadata attributes.

@char (complex table attributes)  
Specifies the alignment character, which is the character that is used for aligning the text in table entries. This attribute applies when align="char". A value of "" (the null string) means there is no aligning character.

For example, if align="char" and char="." are specified, then text in the table entry aligns with the first occurrence of the period within the entry. This might be useful if decimal alignment is required.

The @char attribute is available on the following table elements: <colspec> and <entry>.

@charoff (complex table attributes)  
Specifies the horizontal offset of the alignment character that is specified by the @char attribute. The value is a greater-than-zero number that is less than or equal to 100. It represents the percentage of the current column width by which the text is offset to the left of the alignment character.

For example, if align="char", char="." and charoff="50" are all specified, then text in the table entry is aligned 50% of the distance to the left of the first occurrence of the period character within the table entry.

The @charoff attribute is available on the following table elements: <colspec> and <entry>.

@chunk (common map attributes)  
Specifies how a processor should render a map or branch of a map. For example, it can be used to specify that individual topic documents should be rendered as a single document, or that a single document with multiple topics should be rendered as multiple documents.

The following values are valid:

combine  
Instructs a processor to combine the referenced source documents for rendering purposes. This is intended for cases where a publishing process normally results in a single output artifact for each source XML document.

split  
Instructs a processor to split each topic from the referenced source document into its own document for rendering purposes. This is intended for cases where a publishing process normally results in a single output artifact for each source XML document, regardless of how many DITA topics exist within each source document.

Processors can also define custom, implementation-specific tokens for this attribute.

For a detailed description of the @chunk attribute and its usage, see Chunking.

@collection-type (common map attributes)  
Specifies how topics or links relate to each other. The processing default is "unordered", although no default is specified in the OASIS-provided grammar files. The following values are valid:

unordered  
Indicates that the order of the child topics is not significant.

sequence  
Indicates that the order of the child topics is significant. Output processors will typically link between them in order.

choice  
Indicates that one of the children should be selected.
family
Indicates a tight grouping in which each of the referenced topics not only relates to the current topic but also relate to each other.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@collection-type
The @collection-type attribute specifies how the children of a <topicref> element relate to their parent and to each other. This attribute, which is set on the parent element, typically is used by processors to determine how to generate navigation links in the rendered topics. For example, a @collection-type value of "sequence" indicates that children of the specifying <topicref> element represent an ordered sequence of topics; processors might add numbers to the list of child topics or generate next/previous links for online presentation. This attribute is available in topics on the <linklist> and <linkpool> elements, where it has the same behavior. Where the @collection-type attribute is available on elements that cannot directly contain elements, the behavior of the attribute is undefined.

Disposition: Unassigned

Comment by Kristen J Eberlein on 28 September 2022
In the definitions of the supported values, do we want to refer to "resources" instead of "topics"? Since we specify that @collection-type specifies "how topics or links relate to each other" ...

Disposition: Unassigned

@colsep (complex table attributes)
Specifies whether to render column separators between table entries. The following values are valid: "0" (no separators) and "1" (separators).

The @colsep attribute is available on the following table elements: <colspec>, <entry>, <table>, and <tgroup>.

@compact
Specifies whether the vertical spacing between list items is tightened. The following values are valid: "yes", "no", and "-dita-use-conref-target". Some DITA processors or output formats might not support the @compact attribute.

@datatype (data-element attributes)
Specifies the type of data contained in the @value attribute or within the <data> element. A typical use of @datatype will be the identifying URI for an XML Schema datatype.

@DITAArchVersion (architectural attributes)
Specifies the version of the DITA architecture that is in use. This attribute is in the namespace http://dita.oasis-open.org/architecture/2005/. This attribute is specified in the topic and map modules, and it uses a default value of the current version of DITA. The current default is "2.0".

@duplicates
Specifies whether duplicate links are removed from a group of links. Duplicate links are links that address the same resource using the same properties, such as link text and link role. How duplicate links are determined is processor-specific. The following values are valid:

  yes
  Specifies that duplicate links are retained.
no
   Specifies that duplicate links are removed.

-dita-use-conref-target
   See Using the -dita-use-conref-target value for more information.

The suggested processing default is "yes" within <linklist> elements and "no" for other links.

Comment by robander on Dec 28 2021
"How duplicate links are determined is processor-specific" ==> this should be included in any
updates to standardize language around "implementation dependent".
Disposition: Unassigned

@encoding (inclusion attributes)

Comment by Kristen J Eberlein on 29 April 2019
Can we replace "should" in the following definition?
Disposition: Unassigned

Specifies the character encoding to use when translating the character data from the referenced
content. The value should be a valid encoding name. If not specified, processors may make attempts
to automatically determine the correct encoding, for example using HTTP headers, through analysis
of the binary structure of the referenced data, or the <?xml?> processing instruction when including
XML as text. The resource should be treated as UTF-8 if no other encoding information can be
determined.

When parse="xml", standard XML parsing rules apply for the detection of character encoding.
The necessity and uses of @encoding for non-standard values of @parse are implementation-
dependent.

@expanse (display attributes)
   Specifies the horizontal placement of the element. The following values are valid:

   column
      Indicates that the element is aligned with the current column margin.

   page
      Indicates that the element is placed on the left page margin for left-to-right presentation or the
      right page margin for right-to-left presentation.

   spread
      Indicates that the object is rendered across a multi-page spread. If the output format does not
      have anything that corresponds to spreads, then "spread" has the same meaning as "page".

   textline
      Indicates that the element is aligned with the left (for left-to-right presentation) or right (for right-
      to-left presentation) margin of the current text line and takes indentation into account.

-dita-use-conref-target
   See Using the -dita-use-conref-target value for more information.

For <table>, in place of the @expanse attribute that is used by other DITA elements, the @pgwide
attribute is used in order to conform to the OASIS Exchange Table Model.

Some processors or output formats might not support all values.

@expiry (date attributes)
   Specifies the date when the information should be retired or refreshed. The date is specified using
the ISO 8601 format: YYYY-MM-DD, where YYYY is the year, MM is the month (01 to 12), and DD is
the day (01-31).
@format (link-relationship attributes)
Specifies the format of the resource that is referenced. See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

@frame (display attributes)
Specifies which portion of a border surrounds the element. The following values are valid:
- **all**
  Indicates that a line is rendered at the top, bottom, left, and right of the containing element.
- **bottom**
  Indicates that a line is rendered at the bottom of the containing element.
- **none**
  Indicates that no lines are rendered.
- **sides**
  Indicates that a line is rendered at the left and right of the containing element.
- **top**
  Indicates that a line is rendered at the top of the containing element.
- **topbot**
  Indicates that a line is rendered at the top and bottom of the containing element.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

Some processors or output formats might not support all values.

@golive (date attributes)
Specifies the publication or general availability (GA) date. The date is specified using the ISO 8601 format: YYYY-MM-DD, where YYYY is the year, MM is the month (01 to 12), and DD is the day (01-31).

@headers
Specifies which entries in the current table provide headers for this cell. The @headers attribute contains an unordered set of unique, space-separated tokens, each of which is an ID reference of an entry from the same table.

@href (link-relationship attributes)
Specifies a reference to a resource. See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

@impose-role
Specifies whether this element will impose its role on elements in a referenced map. The attribute is ignored if the target of the reference is not a map or branch of a map. The following values are valid:
- **keeptarget**
  The role of the current reference is not imposed on the target of the reference. This is the default for the unspecialized `<topicref>` element and for many convenience elements such as `<keydef>`.
- **impose**
  The role of the current reference is imposed on the target of the reference. For example, if a specialized topic reference `<chapter>` uses this value and references a map, a topic reference that resolves in place of the `<chapter>` will be treated as if it were a chapter.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.
@keycol (simpletable attributes)
Specifies the column that contains the content that represents the key to the tabular structure. If @keycol is present and assigned a numerical value, the specified column is treated as a vertical header.

@keyref
Specifies a key name that acts as a redirectable reference based on a key definition within a map. See B.4 STUB CONTENT (46) for information on using this attribute.

For HDITA, the equivalent of @keyref is @data-keyref

Comment by robander
The definition above for @keyref should be synchronized with the definition in the linked section on keys.
Disposition: Unassigned

@keys
Specifies one or more names for a resource. See B.4 STUB CONTENT (46) for information on using this attribute.

For HDITA, the equivalent of @keys is @data-keys

@keyscope (common map attributes)
Specifies that the element marks the boundaries of a key scope.

See B.4 STUB CONTENT (46) for information on using this attribute.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@keyscope
Defines a new scope for key definition and resolution, and gives the scope one or more names. For more information about key scopes, see Indirect key-based addressing.

Disposition: Unassigned

@linking (common map attributes)
Specifies linking characteristics of a topic specific to the location of this reference in a map. If the value is not specified locally, the value might cascade from another element in the map (for cascade rules, see Cascading of metadata attributes in a DITA map).

Comment by robander on Dec 28 2021
The text below matches 1.3 spec text but I’m nervous about "cannot link" type definition. It's describing how to generate links based on the current context in the map - it's not describing what the topic itself is allowed to link to, which is how I interpret "can".

Disposition: Unassigned

The following values are valid:

targetonly
A topic can only be linked to and cannot link to other topics.

sourceonly
A topic cannot be linked to but can link to other topics.

normal
A topic can be linked to and can link to other topics. Use this to override the linking value of a parent topic.
none
A topic cannot be linked to or link to other topics.

-dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@linking
By default, the relationships between the topics that are referenced in a map are reciprocal:

• Child topics link to parent topics and vice versa.
• Next and previous topics in a sequence link to each other.
• Topics in a family link to their sibling topics.
• Topics referenced in the table cells of the same row in a relationship table link to each other. A topic referenced within a table cell does not (by default) link to other topics referenced in the same table cell.

This behavior can be modified by using the @linking attribute, which enables an author or information architect to specify how a topic participates in a relationship. The following values are valid:

linking="none"
Specifies that the topic does not exist in the map for the purposes of calculating links.

linking="sourceonly"
Specifies that the topic will link to its related topics but not vice versa.

linking="targetonly"
Specifies that the related topics will link to it but not vice versa.

linking="normal"
Default value. It specifies that linking will be reciprocal (the topic will link to related topics, and they will link back to it).

Authors also can create links directly in a topic by using the <xref> or <link> elements, but in most cases map-based linking is preferable, because links in topics create dependencies between topics that can hinder reuse.

Note that while the relationships between the topics that are referenced in a map are reciprocal, the relationships merely imply reciprocal links in generated output that includes links. The rendered navigation links are a function of the presentation style that is determined by the processor.

Disposition: Unassigned

@name (data-element attributes)
Defines a unique name for the object.

Comment by robander
Do we need to specify the scope of "unique" here?
Disposition: Unassigned

@otherrole
Specifies an alternate role for a link relationship when the @role attribute is set to "other".

@parse (inclusion attributes)
Specifies the processing expectations for the referenced resource. Processors must support the following values:
The contents should be treated as plain text. Reserved XML characters should be displayed, and not interpreted as XML markup.

The contents of the referenced resource should be treated as an XML document, and the referenced element should be inserted at the location of the `<include>` element. If a fragment identifier is included in the address of the content, processors must select the element with the specified ID. If no fragment identifier is included, the root element of the referenced XML document is selected. Any grammar processing should be performed during resolution, such that default attribute values are explicitly populated. Prolog content must be discarded.

It is an error to use `parse="xml"` anywhere other than within `<foreign>` or a specialization thereof.

Processors may support other values for the `@parse` attribute with proprietary processing semantics. Processors should issue warnings and use `<fallback>` when they encounter unsupported `@parse` values. Non-standard `@parse` instructions should be expressed as URIs.

Note Proprietary `@parse` values will likely limit the portability and interoperability of DITA content, so should be used with care.

@processing-role (common map attributes)
Specifies whether the referenced resource is processed normally or treated as a resource that is only included in order to resolve references, such as key or content references. The following values are valid:

normal
Indicates that the resource is a readable part of the information set. It is included in navigation and search results. This is the default value for the `<topicref>` element.

resource-only
Indicates that the resource should be used only for processing purposes. It is not included in navigation or search results, nor is it rendered as a topic. This is the default value for the `<keydef>` element.

@dita-use-conref-target
See Using the `-dita-use-conref-target` value for more information.

If no value is specified but the attribute is specified on a containing element within a map or within the related-links section, the value cascades from the closest containing element.

@relcolwidth (simpletable attributes)
Specifies the width of each column in relationship to the width of the other columns. The value is a space-separated list of relative column widths. Each column width is specified as a positive integer or decimal number followed by an asterisk character.

For example, the value `relcolwidth="1* 2* 3*"` gives a total of 6 units across three columns. The relative widths are 1/6, 2/6, and 3/6 (16.7%, 33.3%, and 50%). Similarly, the value `relcolwidth="90* 150*"` causes relative widths of 90/240 and 150/240 (37.5% and 62.5%).

@role
Specifies the role that a linked topic plays in relationship with the current topic.

For example, in a parent/child relationship, the role would be "parent" when the target is the parent of the current topic, and "child" when the target is the child of the current topic. This can be used to sort and classify links when rendering.

The following values are valid:
ancestor
  Indicates a link to a topic above the parent topic.

cousin
  Indicates a link to another topic in the same hierarchy that is not a parent, child, sibling, next, or previous.

descendant
  Indicates a link to a topic below a child topic.

friend
  Indicates a link to a similar topic that is not necessarily part of the same hierarchy.

next
  Indicates a link to the next topic in a sequence.

other
  Indicates any other kind of relationship or role. The type of role is specified as the value for the @otherrole attribute.

parent
  Indicates a link to a topic that is a parent of the current topic.

previous
  Indicates a link to the previous topic in a sequence.

sibling
  Indicates a link between two children of the same parent topic.

@dita-use-conref-target
  See Using the -dita-use-conref-target value for more information.

@rowheader (complex table attributes)
  Specifies whether the entries in the respective column are row headers. The following values are valid:

  firstcol
    Indicates that entries in the first column of the table are row headers. This applies when the @rowheader attribute is specified on the <table> element.

  headers
    Indicates that entries of the column that is described using the <colspec> element are row headers. This applies when the @rowheader attribute is specified on the <colspec> element.

  norowheader
    Indicates that entries in the first column are not row headers. This applies when the @rowheader attribute is specified on the <table> element.

@dita-use-conref-target
  See Using the -dita-use-conref-target value for more information.

  Note  This attribute is not part of the OASIS Exchange Table Model upon which DITA tables are based. Some processors or output formats might not support all values.

  The @rowheader attribute is available on the following table elements: <table> and <colspec>.

@rowsep (complex table attributes)
  Specifies whether to render row separators between table entries. The following values are valid: "0" (no separators) and "1" (separators).
The @rowsep attribute is available on the following table elements: <colspec>, <entry>, <row>, <table>, and <tgroup>.

@scale (display attributes)
Specifies the percentage by which fonts are resized in relation to the normal text size. The value of this attribute is a positive integer. When used on <table> or <simpletable>, the following values are valid: "50", "60", "70", "80", "90", "100", "110", "120", "140", "160", "180", "200", and -dita-use-conref-target (46).

This attribute is primarily useful for print-oriented display. Some processors might not support all values.

If the @scale attribute is specified on an element that contains an image, the image is not scaled. The image is scaled only if a scaling property is explicitly specified for the <image> element.

@scope (link-relationship attributes)
Specifies the closeness of the relationship between the current document and the referenced resource. The following values are valid: "local", "peer", "external", and -dita-use-conref-target.

See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

@scope
Specifies that the current entry is a header for other table entries. The following values are valid:
  col
    Indicates that the current entry is a header for all cells in the column.
  colgroup
    Indicates that the current entry is a header for all cells in the columns that are spanned by this entry.
  row
    Indicates that the current entry is a header for all cells in the row.
  rowgroup
    Indicates that the current entry is a header for all cells in the rows that are spanned by this entry.

@dita-use-conref-target
See Using the -dita-use-conref-target value for more information.

@search (common map attributes)
Specifies whether the target is available for searching. If the value is not specified locally, the value might cascade from another element in the map (for cascade rules, see Cascading of metadata attributes in a DITA map). The following values are valid: "yes", "no", and -dita-use-conref-target.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:
  @search
    Specifies whether the topic is included in search indexes.
 Disposition: Unassigned

@specializations (architectural attributes)
Specifies the attribute-domain specializations that are included in the document-type shell. This attribute is set as a default within the document-type shell. The value varies depending on what domains are integrated into the document-type shell. For example, a grammar file that includes the specialized attributes @audience, @deliveryTarget, and @newBaseAtt would set the value to @props/audience @props/deliveryTarget @base/newBaseAtt.
@subjectrefs (common map attributes)
   Specifies one or more keys that are each defined by a subject definition in a subject scheme map. Multiple values are separated by white space.

@title-role (REQUIRED)
   Specifies the role that the alternative title serves. Multiple roles are separated by white space. The following roles are defined in the specification: "linking", "navigation", "search", "subtitle", and "hint".

   Processors can define custom values for the @title-role attribute.

@toc (common map attributes)
   Specifies whether a topic appears in the table of contents (TOC) based on the current map context. If the value is not specified locally, the value might cascade from another element in the map (for cascade rules, see Cascading of metadata attributes in a DITA map). The following values are valid:

   yes
       The topic appears in a generated TOC.

   no
       The topic does not appear in a generated TOC.

@dita-use-conref-target
   See B.4 STUB CONTENT (46) for more information.

Comment by Kristen J Eberlein on 28 September 2022
Here is the content from the "DITA map attributes" topic:

@toc
   Specifies whether topics are excluded from navigation output, such as a Web site map or an online table of contents. By default, <topicref> hierarchies are included in navigation output; relationship tables are excluded.

Disposition: Unassigned

@type (link-relationship attributes)
   Describes the target of a reference. See B.4 STUB CONTENT (46) for detailed information on supported values and processing implications.

@value (data-element attributes)
   Specifies a value associated with the current property or element.

@valign (complex table attributes)
   Specifies the vertical alignment of text in table entries. The following values are valid:

   bottom
       Indicates that text is aligned with the bottom of the table entry.

   middle
       Indicates that text is aligned with the middle of the table entry.

   top
       Indicates that text is aligned with the top of the table entry.

@dita-use-conref-target
   See Using the -dita-use-conref-target value for more information.

The @valign attribute is available on the following table elements: <entry>, <tbody>, <thead>, and <row>.

@xml:space
   Specifies how to handle white space in the current element. This attribute is provided on <pre>, <lines>, and on elements specialized from those. It ensures that parsers respect white space that
is part of the data in those elements, including line-end characters. When defined, it has a fixed value of "preserve", making it a default property of the element that cannot be changed or deleted by authors.

@xmlns:ditaarch (architectural attributes)
Declares the default DITA namespace. This namespace is declared as such in the RNG modules for \texttt{<topic> and <map>}, but it is specified as an attribute in the equivalent DTD-based modules. The value is fixed to "http://dita.oasis-open.org/architecture/2005/".
